| 28      | ACTS     | Automatic CTS.<br>The UART_CTL.ACTS bit must be set to enable the $\overline{\text{UART\_CTS}}$ input pin for $\overline{\text{UART\_TX}}$ handshaking. If enabled, the UART_STAT.CTS bit holds the value (if UART_CTL.FCPOL is set) or complement value (if UART_CTL.FCPOL is cleared) of the $\overline{\text{UART\_CTS}}$ input pin. The UART_STAT.CTS bit can be used to determine whether the external device is ready to receive data (if UART_STAT.CTS set) or whether it is busy (if UART_STAT.CTS cleared). If UART_CTL.ACTS is cleared, the $\overline{\text{UART\_TX}}$ handshaking protocol is disabled, and the $\overline{\text{UART\_TX}}$ line transmits data whenever there is data to send, regardless of the value of $\overline{\text{UART\_CTS}}$ . Software can pause ongoing transmission by setting the UART_CTL.XOFF bit. |                                  |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Disable TX handshaking protocol  |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Enable TX handshaking protocol   |
| 27      | ARTS     | Automatic RTS.<br>The UART_CTL.ARTS bit must be set to enable the $\overline{\text{UART\_RTS}}$ input pin for $\overline{\text{UART\_TX}}$ handshaking.If set, hardware guarantees minimal $\overline{\text{UART\_RTS}}$ pin de-assertion pulse width of at least the number of data bits defined by the UART_CTL.WLS bit field. If cleared, the $\overline{\text{UART\_RTS}}$ pin is not generated automatically by hardware. The $\overline{\text{UART\_RTS}}$ pin can still be manually controlled by the UART_CTL.MRTS bit, and software is responsible for $\overline{\text{UART\_RTS}}$ pulse width control (if needed).                                                                                                                                                                                                                     |                                  |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Disable RX handshaking protocol. |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Enable RX handshaking protocol.  |
| 26      | XOFF     | Transmitter off.<br>The UART_CTL.XOFF bit (if set) turns off transmission (XOFF) by preventing the content of THR from being continued to TSR. When set, this bit turns on transmission (XON). The state of the UART_CTL.XOFF bit is ignored if the UART_CTL.ACTS bit is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                  |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Transmission ON, if ACTS=0       |

| 22      | FCPOL    | Flow Control Pin Polarity.<br>The <code>UART_CTL.FCPOL</code> select the polarities of the <code>UART_CTS</code> and <code>UART_RTS</code> pins. When <code>UART_CTL.FCPOL</code> is cleared, the <code>UART_RTS</code> and <code>UART_CTS</code> pins are active low, and UART is halted when the <code>UART_RTS</code> and <code>UART_CTS</code> pin state is high. When <code>UART_CTL.FCPOL</code> is set, the <code>UART_RTS</code> and <code>UART_CTS</code> pins are active high, and UART is halted when the <code>UART_RTS</code> and <code>UART_CTS</code> pin state is low. |
|         |          | 0 Active low CTS/RTS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|         |          | 1 Active high CTS/RTS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 19      | SB       | Set Break.<br>If set, the <code>UART_CTL.SB</code> bit forces the <code>UART_TX</code> pin to low asynchronously, regardless of whether or not data is currently transmitted. This bit functions even when the UART clock is disabled. Because the <code>UART_TX</code> pin normally drives high, it can be used as a flag output pin, if the UART is not used. (For example, if <code>UART_CTL.TPOLC</code> is cleared, drive <code>UART_TX</code> pin low; or if <code>UART_CTL.TPOLC</code> is set, drive <code>UART_TX</code> pin high.)                                           |

| 16      | STP      | Sticky Parity.<br>The <code>UART_CTL.STP</code> bit controls whether the parity is generated by hardware based on the data bits or whether it is set to a fixed value. If this bit is cleared, the hardware calculates the parity bit value based on the data bits. Then, the EPS bit determines whether odd or even parity mode is chosen. If this bit is set, odd parity is used. That means that the total count of logical-1 data bits including the parity bit must be an odd value. Even parity is chosen by <code>UART_CTL.STP</code> cleared and <code>UART_CTL.EPS</code> set. Then, the count of logical-1 bits must be a even value. If the <code>UART_CTL.STP</code> bit is set, hardware parity calculation is disabled. In this case, the sent and received parity equals the inverted <code>UART_CTL.EPS</code> bit. |                                                                |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | No Forced Parity                                               |

| 14      | PEN      | Parity Enable.<br>The <code>UART_CTL.PEN</code> enables parity transmission and parity check. The <code>UART_CTL.PEN</code> bit inserts one additional bit between the most significant data bit and the first stop bit. The polarity of this so-called parity bit depends on data and the <code>UART_CTL.STP</code> and <code>UART_CTL.EPS</code> control bits. Both transmitter and receiver calculate the parity value. The receiver compares the received parity bit with the expected value and issues a parity error if they don't match. If <code>UART_CTL.PEN</code> is cleared, the <code>UART_CTL.STP</code> and the <code>UART_CTL.EPS</code> bits are ignored.                                                                                                                                                          |                                                                |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Disable                                                        |

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |         |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 1       | LOOP_EN  | Loopback Enable.<br>The <code>UART_CTL.LOOP_EN</code> enables UART loopback mode. When set, this bit disconnects the receiver's input from the <code>UART_RX</code> pin, and internally redirects the transmit output to the receiver. The <code>UART_TX</code> pin remains active and continues to transmit data externally as well. Loopback mode also forces the <code>UART_RTS</code> pin to its de-assertive state, disconnects the <code>UART_CTS</code> bit from the <code>UART_CTS</code> input pin, and directly connects the <code>UART_CTL.MRTS</code> bit to the <code>UART_STAT.CTS</code> bit. In loopback mode, setting the <code>UART_CTL.MRTS</code> bit sets the <code>UART_STAT.CTS</code> bit and enables the UART's transmitter. Clearing to the <code>UART_CTL.MRTS</code> bit clears the <code>UART_STAT.CTS</code> bit and disables the UART's transmitter. |         |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Disable |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Enable  |
| 0       | EN       | Enable UART.<br>The <code>UART_CTL.EN</code> enables UART clocks. This bit also resets the state machine and control registers when cleared. Using this bit to disable the UART -- when not used -- reduces power consumption.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |         |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Disable |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Enable  |

## Status Register

The `UART_STAT` register contains the UART line status and UART modem status, as indicated by the current states of the UART's `UART_CTS` pin and internal receive buffers. Writes to this register can perform write-one-to-clear (W1C) operations on most status bits. Reading this register has no side effects.

UART\_STAT: Status Register - R/W

Reset = 0x0000 00a0

**Table 19-11:** UART\_STAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                          |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| 16      | CTS      | Clear to Send.<br>The <code>UART_STAT.CTS</code> bit holds the value (if <code>UART_CTL.FCPOL</code> set) or the complement value (if <code>UART_CTL.FCPOL</code> cleared) of the <code>UART_CTS</code> input pin. The <code>UART_CTL.ACTS</code> bit must be set to enable this feature. The core can read the value of the <code>UART_STAT.CTS</code> bit to determine whether the external device is ready to receive ( <code>UART_STAT.CTS</code> set) or if it is busy ( <code>UART_STAT.CTS</code> cleared). If <code>UART_CTL.ACTS</code> is cleared, the <code>UART_TX</code> handshaking protocol is disabled, and the UART transmits data as long as there is data to transmit, regardless of the value of <code>UART_STAT.CTS</code> . When <code>UART_CTL.ACTS</code> is cleared, the software can pause transmission temporarily by setting the <code>XOFF</code> bit. Note that in loopback mode ( <code>UART_CTL.LOOP_EN</code> set), the <code>UART_STAT.CTS</code> bit is disconnected from the <code>UART_CTS</code> input pin. Instead, the bit is directly connected to the <code>UART_CTL.MRTS</code> bit. |                                                          |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Not clear to send (External device not ready to receive) |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Clear to send (External device ready to receive)         |
| 12      | SCTS     | Sticky CTS.<br>The <code>UART_STAT.SCTS</code> bit is a sticky bit that is set when <code>UART_STAT.CTS</code> transitions from 0 to 1. The <code>UART_STAT.SCTS</code> bit is cleared by software with a <code>W1C</code> operation. This bit can trigger a line status interrupt if enabled by the <code>UART_IMSK_SET.EDSSI</code> bit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                          |

| 10      | ADDR     | Address Bit Status.<br>The <code>UART_STAT.ADDR</code> bit is used to mirror the address bit of the word in <code>UART_RBR</code> in multi-drop bus protocol, and is enabled only in MDB mode. The <code>UART_STAT.ADDR</code> bit is updated by hardware upon detecting a received word with the address bit in <code>UART_RBR</code> set or cleared. Additionally, software can set the ADDR bit with a write-1-to-set (W1S) operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|         |          | 1 Address bit is high                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 9       | ASTKY    | Address Sticky.<br>The <code>UART_STAT.ASTKY</code> bit is used in multi-drop bus mode to indicate whether a peripheral is currently being addressed. This bit is a sticky version of the <code>UART_STAT.ADDR</code> bit and is set by hardware when setting the <code>UART_STAT.ADDR</code> bit. The <code>UART_STAT.ASTKY</code> bit can only be cleared by software with a write-one-to-clear (W1C) operation. With the <code>UART_STAT.ASTKY</code> bit set, words will be received irrespective of the <code>UART_CTL.MOD</code> bit or <code>UART_STAT.ADDR</code> bit selection. With the <code>UART_STAT.ASTKY</code> bit cleared, only address words ( <code>UART_CTL.MOD</code> bit set) will be received and words with <code>UART_CTL.MOD</code> bit cleared are ignored (not moved from the RSR to the RX FIFO) in MDB mode. The <code>UART_STAT.ASTKY</code> bit does not affect reception in non-MDB modes. |
|         |          | 0 ADDR bit has not been set                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|         |          | 1 ADDR bit has been set                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 8       | TFI      | Transmission Finished Indicator.<br>The <code>UART_STAT.TFI</code> bit is a sticky version of the <code>UART_STAT.TEMT</code> bit. While <code>UART_STAT.TEMT</code> is automatically cleared by hardware when new data is written to the <code>UART_THR</code> register, the sticky <code>UART_STAT.TFI</code> bit remains set, until it is cleared by software (W1C). The <code>UART_STAT.TFI</code> bit enables more flexible transmit interrupt timing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7       | TEMT     | TSR and THR Empty.<br>The UART_STAT.TEMT bit indicates that the UART_THR and UART_TAIP registers and the UART_TSR register are empty. In this case, the program is permitted to write to the UART_THR and UART_TAIP registers twice without losing data. The UART_STAT.TEMT bit can also be used as indicator that pending UART transmission is completed. At that time, it is safe to disable the UART_CTL.EN bit or to three-state the off-chip line driver.                                                                |

| 2       | PE       | Parity Error.<br>The <code>UART_STAT.PE</code> bit indicates that the received parity bit does not match the expected value. This bit is updated simultaneously with the <code>UART_STAT.DR</code> bit, that is, by the time the first stop bit is received or when data is loaded from the receive FIFO to the <code>UART_RBR</code> register. The <code>UART_STAT.PE</code> bit is sticky and can be cleared by W1C operations. Note that invalid parity bits can be simulated by setting the <code>UART_CTL.FPE</code> bit.                                                                                                                                                                                 |                        |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | No parity error        |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Parity error           |
| 1       | OE       | Overrun Error.<br>The <code>UART_STAT.OE</code> bit indicates that further data is received while the internal receive buffer was full. This bit is set when sampling the stop bit of the sixth data word. To avoid overruns, read the <code>UART_RBR</code> register in time. In DMA receive mode, overruns are very unlikely to happen ever. After an overrun occurs, the <code>UART_RBR</code> and receive FIFO are protected from being overwritten by new data until the <code>UART_STAT.OE</code> bit is cleared by software. The content of the <code>UART_RSR</code> register is lost as soon as the overrun occurs. The <code>UART_STAT.OE</code> bit is sticky and can be cleared by W1C operations. |                        |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | No overrun             |

## Scratch Register

The UART\_SCR registers contain 8-bit scratch pad data. These registers are used for general purpose data storage and do not control the UART hardware in any way.

### UART\_SCR: Scratch Register - R/W

Reset = 0x0000 0000

**Figure 19-17:** UART\_SCR Register Diagram

**Table 19-12:** UART\_SCR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 7:0     | VALUE    | Stored 8-bit Data.      |

## Clock Rate Register

The UART\_CLK register divides the system clock (SCLK) down to the bit clock.

UART\_CLK: Clock Rate Register - R/W

Reset = 0x0000 ffff

Interrupt Mask Register

The UART\_IMSK indicates interrupt mask status (unmasked if set, masked if cleared) of UART status interrupts. This register is not a data register. Instead it is controlled by the UART\_IMSK\_SET and UART\_IMSK\_CLR register pair. Writing ones to UART\_IMSK\_SET enables (unmasks) interrupts, and writing ones to UART\_IMSK\_CLR disables (masks) them. Reads from either register return the enabled bits.

The UART\_IMSK register is used to enable requests for system handling of empty or full states of UART data registers. Unless polling is used as a means of action, the UART\_IMSK.ERBFI and/or UART\_IMSK.ETBEI bits are normally set. Setting this register without enabling system DMA causes the UART to notify the processor of data inventory state by means of interrupts. For proper operation in this mode, system interrupts must be enabled, and appropriate interrupt handling routines must be present.

Each UART features three separate interrupt channels to handle data transmit, data receive, and line status events independently, regardless whether DMA is enabled or not. If no DMA channels are assigned to the UART, set the `UART_IMSK.ELSI` bit to reroute transmit and receive interrupts to the status interrupt output.

With system DMA enabled, the UART uses DMA to transfer data to or from the processor. Dedicated DMA channels are available to receive and transmit operation. Line error handling can be configured completely independently from the receive/transmit setup.

The UART's DMA is enabled by first setting up the system DMA control registers and then enabling the `UART_IMSK.ERBFI` and/or `UART_IMSK.ETBEI` interrupts. This is because the interrupt request lines double as DMA request lines. Depending on whether DMA is enabled or not, upon receiving these requests, the DMA control unit either generates a direct memory access or passes the UART interrupt on to the system interrupt handling unit. However, UART's error interrupt goes directly to the system interrupt handling unit, bypassing the DMA unit completely.

#### UART\_IMSK: Interrupt Mask Register - R/W

Reset = 0x0000 0000

|         |          | 1                      Interrupt is unmasked                                                                                                                                                                                                                                                                                    |

**Table 19-14:** UART\_IMSK Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5       | ETFI     | Enable Transmission Finished Interrupt Mask Status.<br>If set (interrupt unmasked) the <code>UART_IMSK.ETFI</code> bit indicates enabling of interrupt generation on the status interrupt channel when the transmit buffer register, the transmit address register, and the transmit shift register are all empty as indicated by the <code>UART_STAT.TFI</code> . The <code>UART_IMSK.ETFI</code> interrupt can be used to avoid expensive polling of the <code>UART_STAT.TEMT</code> bit, when the UART clock or line drivers should be disabled after transmission has completed. W1C the <code>UART_STAT.TFI</code> bit to clear the interrupt request. In DMA operation, the <code>UART_IMSK.ETFI</code> bit's functionality might be preferred.                                                                                                                                                            |
|         |          | 0 Interrupt is masked                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|         |          | 1 Interrupt is unmasked                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 4       | EDTPTI   | Enable DMA TX Peripheral Triggerred Interrupt Mask Status.<br>If set (interrupt unmasked), the <code>UART_IMSK.EDTPTI</code> bit indicates enabling of the DMA completion interrupt to be delayed until the data has left the UART completely. This bit is required for DMA transmit operation only. If set, the UART can generate a DMA interrupt by the time the <code>UART_STAT.TEMT</code> bit goes high after the last DMA data word is transmitted.<br>When <code>UART_IMSK.EDTPTI</code> is set, usually the <code>DDE_CFG_INT</code> field is cleared to "00" in a STOP mode DMA. This set up suppresses the normal completion interrupt, and the <code>UART_STAT.TEMT</code> event is signaled through the DMA controller and triggers the DMA interrupt. If both ( <code>DDE_CFG_INT</code> not 00 and <code>UART_IMSK.EDTPTI</code> set), two interrupts are requested at the end of a STOP mode DMA. |
|         |          | 0 Interrupt is masked                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|         |          | 1 Interrupt is unmasked                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Table 19-14:** UART\_IMSK Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3       | EDSSI    | Enable Modem Status Interrupt Mask Status.<br>If set (interrupt unmasked), the <code>UART_IMSK.EDSSI</code> bit indicates enabling of a modem status interrupt on the same status interrupt channel when the <code>UART_STAT.SCTS</code> bit is set. This indicates <code>UART_CTS</code> pin re-assertion. Write-1-to-clear (W1C) the <code>UART_STAT.SCTS</code> bit to clear the interrupt request.                                                                                                                                                                        |
|         |          | 0 Interrupt is masked                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|         |          | 1 Interrupt is unmasked                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 2       | ELSI     | Enable Line Status Interrupt Mask Status.<br>If set (interrupt unmasked), the <code>UART_IMSK.ELSI</code> bit indicates that redirection of TX and RX interrupt requests to the status interrupt output of the UART by OR'ing them with the <code>UART_STAT.OE</code> , <code>UART_STAT.PE</code> , <code>UART_STAT.FE</code> , and <code>UART_STAT.BI</code> interrupt requests. Set this bit when no DMA channel is associated with the UART. Enabling <code>UART_IMSK.ELSI</code> disables the RX/TX interrupt channels and negates the <code>UART_IMSK.EDTPTI</code> bit. |
|         |          | 0 Interrupt is masked                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Interrupt Mask Set Register

The UART\_IMSK indicates interrupt mask status (unmasked if set, masked if cleared) of UART status interrupts. This register is not a data register. Instead it is controlled by the UART\_IMSK\_SET and UART\_IMSK\_CLR register pair. Writing ones to UART\_IMSK\_SET enables (unmasks) interrupts, and writing ones to UART\_IMSK\_CLR disables (masks) them. Reads from either register return the enabled bits. For more information, see the UART\_IMSK register description.

|         |          | 1 Unmask interrupt                             |

## Interrupt Mask Clear Register

The UART\_IMSK indicates interrupt mask status (unmasked if set, masked if cleared) of UART status interrupts. This register is not a data register. Instead it is controlled by the UART\_IMSK\_SET and UART\_IMSK\_CLR register pair. Writing ones to UART\_IMSK\_SET enables (unmasks) interrupts, and writing ones to UART\_IMSK\_CLR disables (masks) them. Reads from either register return the enabled bits. For more information, see the UART\_IMSK register description.

### UART\_IMSK\_CLR: Interrupt Mask Clear Register - R/W

Reset = 0x0000 0000

|         |          | 0 No action                                        |
|         |          | 1 Mask interrupt                                   |

## Receive Buffer Register

The read-only `UART_RBR` register is the UART's receive buffer. It is updated when there is pending data in the receive FIFO. Newly available data is signaled by the `UART_STAT.DR` bit.

### UART\_RBR: Receive Buffer Register - R/WE

Reset = 0x0000 0000

**Figure 19-22:** UART\_RBR Register Diagram

**Table 19-17:** UART\_RBR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 7:0     | VALUE    | 8-bit data.             |

## Transmit Hold Register

The write-only `UART_THR` register is the UART's transmit buffer. The `UART_STAT.THRE` bit indicates whether data can be written to `UART_THR`. Writes to this register automatically propagate to the internal `UART_TSR` register as soon as `UART_TSR` is ready. Then, transmit operation is initiated immediately.

**UART\_THR: Transmit Hold Register - R/W**

Reset = 0x0000 0000

**Figure 19-23:** UART\_THR Register Diagram

**Table 19-18:** UART\_THR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 7:0     | VALUE    | 8 bit data.             |

## Transmit Address/Insert Pulse Register

The `UART_TAIP` register and the `UART_THR` register share the same physical register, but `UART_TAIP` has different effect than the `UART_THR` register when `UART_TAIP` is written to in MDB and UART modes.

In MDB mode, data written to the `UART_TAIP` register is transmitted as an address frame (as with the `UART_CTL.MOD` bit set).

In UART mode, a write to `UART_TAIP` causes a pulse of value `UART_TAIP` [7] for a duration of `UART_TAIP` [6:0] x bit time. (There is additional inversion if the `UART_CTL.TPOLC` bit is set).

Bit time is defined by the `UART_CLK` register. The transmission of the pulse is followed by stop bit transmission as specified by the `UART_CTL.STB` and `UART_CTL.STBH` bits. This could be used for supporting line break command and inter-frame gap.

In IrDA mode, writes to `UART_TAIP` is treated the same as writes to `UART_THR`.

Accesses to the `UART_TAIP` register have the same affects as the `UART_THR` register with respect to the `UART_STAT.THRE`, `UART_STAT.TEMT`, and `UART_STAT.TFI` flags.

**UART\_TAIP: Transmit Address/Insert Pulse Register - R/W**

Reset = 0x0000 0000

**Figure 19-24:** UART\_TAIP Register Diagram

**Table 19-19:** UART\_TAIP Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 7:0     | VALUE    | 8-bit data.             |

## Transmit Shift Register

The read only `UART_TSR` register which returns the content of the UART's transmit shift register.

**UART\_TSR: Transmit Shift Register - R/WE**

Reset = 0x0000 07ff

**Figure 19-25:** UART\_TSR Register Diagram

**Table 19-20:** UART\_TSR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 10:0    | VALUE    | Contents of TSR.        |

## Receive Shift Register

The read only `UART_RSR` register which returns the content of the UART's receive shift register.

The frame data is moved into this shift register after polarity inversion, if any (including the native polarity inversion in the IrDA case).

In the case of the longest frame (MDB, with parity mode, and 8 bit data word-length), the start bit may be shifted out and not available for reading at the end of the frame reception. This register is NOT reset at the start of frame. If read, in the middle of a frame reception, data corresponding the previous frame may not have entirely shifted out (for example, the read data that have been read may NOT correspond entirely to the frame being received).

Because the UART is receiving only 1 stop bit, the `UART_RSR` contains only 1 stop bit even if more than one stop bit is present in the actual transfer. This register may be considered as storing the 10 most recently received bits (taking into consideration the stop bit receive limitation above).

Figure 19-26: UART\_RSR Register Diagram

Table 19-21: UART\_RSR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 9:0     | VALUE    | Contents of RSR.        |

Transmit Counter Register

The `UART_TXCNT` read only register returns the content of 16-bit counter in the UART transmitter. This count is used for baud rate clock generation (the lower [15:0] is the count data).

**UART\_TXCNT: Transmit Counter Register - R/WE**

Reset = 0x0000 0000

**Figure 19-27:** UART\_TXCNT Register Diagram

**Table 19-22:** UART\_TXCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 15:0    | VALUE    | 16-bit Counter Value.   |

## Receive Counter Register

The `UART_RXCNT` register returns the content of 16-bit counter in the UART receiver. This count is used for baud rate clock generation (the lower [15:0] is the count data).

**UART\_RXCNT: Receive Counter Register - R/WE**

Reset = 0x0000 0000

**Table 19-23:** UART\_RXCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 15:0    | VALUE    | 16-bit Counter Value.   |

## 20 2-Wire Interface (TWI)

The processors include a 2-wire interface (TWI), providing a simple exchange method of control data between multiple devices. The TWI module is compatible with the widely used I<sup>2</sup>C bus standard. The TWI module offers the capabilities of simultaneous master and slave operation and support for both 7-bit addressing and multimedia data arbitration. The TWI interface utilizes two pins for transferring clock (TWI\_SCL) and data (TWI\_SDA) and supports the protocol at speeds up to 400k bits/sec. The TWI interface pins are compatible with 5 V logic levels.

Additionally, the TWI module is fully compatible with serial camera control bus (SCCB) functionality for easier control of various CMOS camera sensor devices.

To preserve processor bandwidth, the TWI module can be set up with transfer initiated interrupts only to service FIFO buffer data reads and writes. Protocol related interrupts are optional. The TWI externally moves 8-bit data while maintaining compliance with the I<sup>2</sup>C bus protocol.

### TWI Features

The TWI is fully compatible with the widely used I<sup>2</sup>C bus standard.

The TWI controller includes these features.

- Simultaneous master and slave operation on multiple device systems
- Support for multi-master bus arbitration
- 7-bit addressing
- 100K bits/second and 400K bits/second data rates
- General call address support
- Master clock synchronization and support for clock low extension
- Separate multiple-byte receive and transmit FIFOs
- Low interrupt rate
- Individual override control of data and clock lines in the event of bus lock-up
- Input filter for spike suppression
- Serial camera control bus support as specified in the *OmniVision Serial Camera Control Bus (SCCB) Functional Specification*

## TWI Functional Description

The TWI interface is a shift register that serially transmits and receives data bits, one bit at a time at the SCL rate, to and from other TWI devices. The SCL signal synchronizes the shifting and sampling of the data on the serial data pin.

## TWI Register List

The 2-wire interface TWI controller allows a device to interface to an inter IC bus as specified by the Philips I<sup>2</sup>C Bus Specification version 2.1 dated January 2000. A set of registers govern TWI operations. For more information on TWI functionality, see the TWI register descriptions.

**Table 20-1:** TWI Module Registers

| Name         | Description                   |
|--------------|-------------------------------|
| TWI_CLKDIV   | SCL Clock Divider Register    |
| TWI_CTL      | Control Register              |
| TWI_SLVCTL   | Slave Mode Control Register   |
| TWI_SLVSTAT  | Slave Mode Status Register    |
| TWI_SLVADDR  | Slave Mode Address Register   |
| TWI_MSTRCTL  | Master Mode Control Registers |
| TWI_MSTRSTAT | Master Mode Status Register   |
| TWI_MSTRADDR | Master Mode Address Register  |
| TWI_ISTAT    | Interrupt Status Register     |
| TWI_IMSK     | Interrupt Mask Register       |
| TWI_FIFOCTL  | FIFO Control Register         |
| TWI_FIFOSTAT | FIFO Status Register          |
| TWI_TXDATA8  | Tx Data Single-Byte Register  |
| TWI_TXDATA16 | Tx Data Double-Byte Register  |
| TWI_RXDATA8  | Rx Data Single-Byte Register  |

| Name         | Description                  |
|--------------|------------------------------|
| TWI_RXDATA16 | Rx Data Double-Byte Register |

## ADSP-BF60x TWI Interrupt List

**Table 20-2:** ADSP-BF60x TWI Interrupt List

| Description         | ID | DMA Channel | Sensitivity |
|---------------------|----|-------------|-------------|
| TWI0 Data Interrupt | 32 |             | LEVEL       |
| TWI1 Data Interrupt | 33 |             | LEVEL       |

## TWI Block Diagram

The following figure shows the basic blocks of the TWI interface.

**Figure 20-1:** TWI Block Diagram

## TWI External Interface

The SDA (serial data) and SCL (serial clock) signals are open drain and require pull-up resistors. These bidirectional signals externally interface the TWI controller to the I<sup>2</sup>C bus. The interface is simple and no other external connections or logic are required.

### Serial Clock Signal (SCL)

The serial clock signal (SCL) is an input in slave mode. In master mode the TWI controller must set this signal to the desired frequency.

The TWI controller supports the standard mode of operation (up to 100 kHz) or fast mode (up to 400 kHz). The TWI control register (CTL) is used to set the PRESCALE value which sets the relationship between the system clock (SCLK) and the TWI controller's internally timed events. The internal time reference is derived from SCLK using a prescaled value. The PRESCALE value is the number of SCLK periods used in the generation of one internal time reference. The value of PRESCALE must be set to create an internal time reference with a period of 10 MHz. It is represented as a 7-bit binary value as shown below.

$$\text{PRESCALE} = f_{\text{SCLK}}/10\text{MHz}$$

During master mode operation, the CLKDIV register values are used to create the minimum CLKHI and CLKLO durations of the serial clock (SCL). The CLKHI field of the CLKDIV register specifies the minimum number of 10 MHz time reference periods the serial clock (SCL) waits before a new clock low period begins, assuming a single master. It is represented as an 8-bit binary value. The CLKLO field of the CLKDIV register specifies the minimum number of internal time reference periods the serial clock (SCL) is held low. It is represented as an 8-bit binary value.

Serial clock frequencies can vary from 400 kHz to less than 20 kHz. The resolution of the clock generated is 1/10 MHz or 100 ns as shown below.

$$\text{CLKDIV} = \text{TWI SCL period} / 10 \text{ MHz time reference.}$$

For example, for an SCL of 400 kHz (period = 1/400 kHz = 2500 ns) and an internal time reference of 10 MHz (period = 100 ns) the following equation is used:

$$\text{CLKDIV} = 2500 \text{ ns} / 100 \text{ ns} = 25$$

Therefore, a SCL with a 30% duty cycle has CLKLO = 17 and CLKHI = 8. Note that CLKLO and CLKHI add up to CLKDIV.

**NOTE:** The CLKHI and CLKLO fields of the CLKDIV register are not intended to guarantee a certain frequency. Rather, they guarantee a certain minimum high and low duration for SCL. Falling edges are controlled by slew rate, and rising edges are governed by the RC time constant formed by the pull-up resistor and the SCL capacitance. See SCL CLKDIV for details.

## Serial Data Signal (SDA)

This is a bidirectional signal on which serial data is transmitted or received depending on the direction of the transfer.

## TWI Internal Interface

The peripheral bus interface supports the transfer of 16-bit wide data and is used by the processor in the support of register and FIFO buffer reads and writes. The TWI internal interface is comprised of the blocks described below.

**Register Block.** Contains all control and status bits and reflects what can be written or read as outlined by the programming model. Status bits can be updated by their respective functional blocks.

**FIFO Buffer.** Configured as a 1-byte-wide 2-deep transmit FIFO buffer and a 1-byte-wide 2-deep receive FIFO buffer.

**Transmit Shift Register.** Serially shifts its data out externally off chip. The output can be controlled for generation of acknowledgments or it can be manually overwritten.

**Receive Shift Register.** Receives its data serially from off chip. The receive shift register is 1 byte wide and data received can either be transferred to the FIFO buffer or used in an address comparison.

**Address Compare Block.** Supports address comparison in the event the TWI controller module is accessed as a slave.

**Prescaler Block.** Must be programmed to generate a 10 MHz time reference relative to the system clock. This time base is used for filtering of data and timing events specified by the electrical data sheet (See the Philips specification), as well as for SCL clock generation.

**Clock Generation Module.** Generates an external SCL clock when in master mode. It includes the logic necessary for synchronization in a multi-master clock configuration and clock stretching when configured in slave mode.

## TWI Architectural Concepts

The TWI controller follows the transfer protocol of the Philips I<sup>2</sup>C Bus Specification version 2.1 dated January 2000.

## TWI Protocol

The following figure shows a simple complete transfer.

To better understand the mapping of TWI controller register contents to a basic transfer, The following figure details the same transfer as above noting the corresponding TWI controller bit names. In this illustration, the TWI controller successfully transmits one byte of data. The slave has acknowledged both address and data.

Figure 20-2: Data Transfer with Bit Illustration

Clock Generation and Synchronization

The TWI controller implementation only issues a clock during master mode operation and only at the time a transfer has been initiated. If arbitration for the bus is lost, the serial clock output immediately three-states. If multiple clocks attempt to drive the serial clock line, the TWI controller synchronizes its clock with the other remaining clocks. This is shown in the figure below.

Figure 20-3: Clock Synchronization

The TWI controller serial clock (SCL) output follows these rules:

- Once the clock high (CLKHI) count is complete, the serial clock output is driven low and the clock low (CLKLO) count begins.
- Once the clock low count is complete, the serial clock line is three-stated, allowing the external pull-up resistor to pull SCL high, and the clock synchronization logic enters into a delay mode (shaded area) until the SCL line is detected at logic 1 level. At this time the clock high count begins.

## Bus Arbitration

The TWI controller initiates a master mode transmission only when the bus is idle. If the bus is idle and two masters initiate a transfer, arbitration for the bus begins. This is shown in the figure below.

**Figure 20-4:** Bus Arbitration

The TWI controller monitors the serial data bus (SDA) while SCL is high and if SDA is determined to be an active logic 0 level while the TWI controller's data is a logic 1 level, the TWI controller has lost arbitration and ends generation of clock and data. Note that arbitration is not only performed at serial clock edges, but also during the entire time SCL is high.

## Start and Stop Conditions

Start and stop conditions involve serial data transitions while the serial clock is a logic 1 level. The TWI controller generates and recognizes these transitions. Typically start and stop conditions occur at the beginning and at the conclusion of a transmission with the exception repeated start “combined” transfers, as shown in the figure below.

**Figure 20-5:** Start and Stop Conditions

The TWI controller's special case start and stop conditions include the following.

- Controller addressed as a slave-receiver. If the master asserts a stop condition during the data phase of a transfer, the TWI controller concludes the transfer (SCOMP).
- Controller addressed as a slave-transmitter. If the master asserts a stop condition during the data phase of a transfer, the TWI controller concludes the transfer (SCOMP) and indicates a slave transfer error (SERR).

- Controller as a master-transmitter or master-receiver. If the stop bit is set during an active master transfer, the TWI controller issues a stop condition as soon as possible avoiding any error conditions (as if data transfer count had been reached).

## General Call Support

The TWI controller always decodes and acknowledges a general call address if it is enabled as a slave and if general call is enabled. General call addressing (0x00) is indicated by the `GCALL` bit being set and by nature of the transfer the TWI controller is a slave-receiver. If the data associated with the transfer is to be NAK'ed, the NAK bit can be set. If the TWI controller is to issue a general call as a master-transmitter the appropriate address and transfer direction can be set along with loading transmit FIFO data.

## Fast Mode

Fast mode essentially uses the same mechanics as the standard mode of operation. It is the electrical specifications and timing that are most affected. When fast mode is enabled (FAST) timing is modified to meet the electrical requirements as described below.

- Serial data rise times before arbitration evaluation ( $t_r$ )
- Stop condition set-up time from serial clock to serial data ( $t_{SUSTO}$ )
- Bus free time between a stop and start condition ( $t_{BUF}$ )

## TWI Operating Modes

The TWI has two modes of operation, *repeated start* and *clock stretching*. These are described in the following sections.

### Repeated Start

A repeated start condition is the absence of a stop condition between two transfers. The two transfers can be of any direction type. Examples include a transmit followed by a receive, or a receive followed by a transmit. The following sections guide the programmer in developing a service routine.

### Transmit Receive Repeated Start

The following figure shows a repeated start followed by a data receive sequence.

The following tasks are performed at each interrupt.

- TXSERV interrupt. This interrupt was generated due to a FIFO access. Since this is the last byte of this transfer, the `FIFOSTAT` register indicates the transmit FIFO is empty. When read, `DCNT` is zero. Set the `RSTART` bit to indicate a repeated start and set the `DIR` bit if the following transfer will be a data receive.
- MCOMP interrupt. This interrupt was generated because all data has been transferred (`DCNT = 0`). If no errors were generated, a start condition is initiated. Clear the `RSTART` bit and program the `DCNT` with the desired number of bytes to receive.
- RXSERV interrupt. This interrupt is generated due to the arrival of a byte in the receive FIFO. Simple data handling is all that is required.
- MCOMP interrupt. The transfer is complete.

## Receive Transmit Repeated Start

The following figure illustrates a repeated start data receive followed by a data transmit sequence. The tasks performed at each interrupt are:

- RXSERV interrupt. This interrupt is generated due to the arrival of a data byte in the receive FIFO. Set the `RSTART` bit to indicate a repeated start and clear the `MDIR` bit if the following transfer will be a data transmit.
- MCOMP interrupt. This interrupt has occurred due to the completion of the data receive transfer. If no errors were generated, a start condition is initiated. Clear the `RSTART` bit and program the `DCNT` with the desired number of bytes to transmit.
- TXSERV interrupt. This interrupt is generated due to a FIFO access. Simple data handling is all that is required.
- MCOMP interrupt. The transfer is complete.

**NOTE:** There is no timing constraint to meet the above conditions—the user can program the bits as required. Refer to “Clock Stretching During Repeated Start Condition” section for more on how the controller stretches the clock during Repeated Start transfers.

## Clock Stretching

Clock stretching is an added function of the TWI controller in master mode operation. This new behavior uses self-induced stretching of the I<sup>2</sup>C clock while waiting on servicing interrupts. Stretching is done automatically by the hardware and no programming is required for this. The TWI Controller as master supports three modes of clock stretching: clock stretching during FIFO Underflow, clock stretching during FIFO overflow and clock stretching during repeated start condition.

Clock Stretching During FIFO Underflow

During a master mode transmit, an interrupt is generated at the instant the transmit FIFO becomes empty. At this time, the most recent byte begins transmission. If the TXSERV interrupt is not serviced, the concluding acknowledge phase of the transfer is stretched. Stretching of the clock continues until new data bytes are written to the transmit FIFO (TXDATA8 or TXDATA16). No other action is required to release the clock and continue the transmission. This behavior continues until the transmission is complete ( DCNT = 0) at which time the transmission is concluded (MCOMP) as shown in the following figure and table.

Figure 20-6: Clock Stretching during FIFO Underflow

| TWI Controller                                            | Processor                                                             |
|-----------------------------------------------------------|-----------------------------------------------------------------------|
| Interrupt: XMTSERV – Transmit FIFO buffer is empty.       | Acknowledge: Clear interrupt source bits. Write transmit FIFO buffer. |
| ...                                                       | ...                                                                   |
| Interrupt: MCOMP – Master transmit complete (DCNT= 0x00). | Acknowledge: Clear interrupt source bits.                             |

Clock Stretching During FIFO Overflow

During a master mode receive, an interrupt is generated at the instant the receive FIFO becomes full. It is during the acknowledge phase of this received byte that clock stretching begins. No attempt is made to initiate the reception of an additional byte. Stretching of the clock continues until the data bytes previously received are read from the receive FIFO buffer (RXDATA8 or RXDATA16). No other action is required to release the clock and continue the reception of data. This behavior continues until the reception is

complete (DCNT = 0x00) at which time the reception is concluded (MCOMP) as shown in the following figure and table.

**Figure 20-7:** Clock Stretching During FIFO Overflow

| TWI Controller                                    | Processor                                                           |
|---------------------------------------------------|---------------------------------------------------------------------|
| Interrupt: RCVSERV – Receive FIFO buffer is full. | Acknowledge: Clear interrupt source bits. Read receive FIFO buffer. |
| ...                                               | ...                                                                 |
| Acknowledge: Clear interrupt source bits.         | Interrupt: MCOMP – Master receive complete.                         |

## Clock Stretching During Repeated Start

The repeated start feature in I2C protocol requires transitioning between two subsequent transfers. With the use of clock stretching, the task of managing transitions becomes simpler and becomes common to all transfer types.

Once an initial TWI master transfer has completed (transmit or receive) the clock initiates a stretch during the repeated start phase between transfers. Concurrent with this event the initial transfer generates a transfer complete interrupt (MCOMP) to signify the initial transfer has completed (DCNT = 0). This initial transfer is handled without any special bit setting sequences or timing. The clock stretching logic described above applies here. With no system related timing constraints the subsequent transfer (receive or transmit) is setup and activated. This sequence can be repeated as many times as required to string a series of repeated start transfers together. This is shown in the following figure and table.

Figure 20-8: Clock Stretching during Repeated Start Condition

| TWI Controller                                                                                                        | Processor                                                                                                                                       |
|-----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| Interrupt: MCOMP – Initial transmit has completed and DCNT = 0x00. Note: transfer in progress, RSTART previously set. | Acknowledge: Clear interrupt source bits. Write TWIx_MASTER_CTL, setting MDIR (receive), clearing RSTART, and setting new DCNT value (nonzero). |
| Interrupt: RCVSERV – Receive FIFO is full.                                                                            | Acknowledge: Clear interrupt source bits. Read receive FIFO buffer.                                                                             |
| ...                                                                                                                   | ...                                                                                                                                             |
| Interrupt: MCOMP – Master receive complete                                                                            | Acknowledge: Clear interrupt source bits.                                                                                                       |

## TWI Programming Model

The topics in this section provide information on the basic programming steps required to set up and run the two wire interface.

The following sections provide general setup, and master and slave mode programming steps.

## TWI General Setup

General setup refers to register writes that are required for both slave mode and master mode operation.

General setup should be performed before either the master or slave enable bits are set.

1. Program the CTL register to enable the TWI controller and set the prescale value.
2. Program the prescale value to the binary representation of  $f_{\text{SCLK}}/10$  MHz. All values should be rounded up to the next whole number.
3. Set the EN bit in the CTL register.

*RESULT:*

Once the TWI controller is enabled a bus busy condition may be detected. This condition should clear after  $t_{\text{BUF}}$  has expired assuming no additional bus activity has been detected.

## Slave Mode

When enabled, slave mode operation supports both receive and transmit data transfers.

It is not possible to enable only one data transfer direction and not acknowledge (NAK) the other. This is reflected in the following setup.

1. Program the SLVADDR register. The appropriate 7 bits are used in determining a match during the address phase of the transfer.
2. Program the TXDATA8 or TXDATA16 registers. These are the initial data values to be transmitted in the event the slave is addressed and a transmit is required. This is an optional step. If no data is written and the slave is addressed and a transmit is required, the serial clock (SCL) is stretched and an interrupt is generated until data is written to the transmit FIFO.
3. Program the IMASK register. Enable bits are associated with the desired interrupt sources. As an example, programming the value 0x000F results in an interrupt output to the processor in the event that a valid address match is detected, a valid slave transfer completes, a slave transfer has an error, a subsequent transfer has begun yet the previous transfer has not been serviced.
4. Program the SLVCTL register. Ultimately this prepares and enables slave mode operation. As an example, programming the value 0x0005 enables slave mode operation, requires 7-bit addressing, and indicates that data in the transmit FIFO buffer is intended for slave mode transmission.

*RESULT:*

The following table and flow diagram shows what the interaction between the TWI controller and the processor might look like using this example.

Figure 20-9: TWI Slave Mode Program Flow

Table 20-3: Slave Mode Interaction

| TWI Controller                                 | Processor                                                                                |
|------------------------------------------------|------------------------------------------------------------------------------------------|
| Interrupt: SINIT – Slave transfer in progress. | Acknowledge: Clear interrupt source bits.                                                |
| Interrupt: RCVSERV – Receive buffer is full.   | Acknowledge: Clear interrupt source bits. Read TWIx_FIFO_STAT. Read receive FIFO buffer. |
| ...                                            | ...                                                                                      |
| Interrupt: SCOMP – Slave transfer complete.    | Acknowledge: Clear interrupt source bits. Read receive FIFO buffer.                      |

## Master Mode Clock Setup

Master mode operation is set up and executed on a per-transfer basis.

An example of programming steps for a receive and for a transmit are given separately in following sections. The clock setup programming step listed here is common to both transfer types.

1. Program `CLKDIV` to define the minimum `CLKHI` duration and minimum `CLKLO` duration.

*RESULT:*

The `CLKHI` and `CLKLO` fields of the `CLKDIV` register are not intended to guarantee a certain frequency. Rather, they guarantee a certain minimum high and low duration for SCL. Falling edges are controlled by slew rate, and rising edges are governed by the RC time constant formed by the pull-up resistor and the SCL capacitance. See SCL clock divider register (`CLKDIV`) for details.

## Master Mode Transmit

Follow these programming steps for a single master mode transmit:

1. Program the `MSTRADDR` register. This defines the address transmitted during the address phase of the transfer.
2. Program the `TXDATA8` or `TXDATA16` register. This is the initial data transmitted. It is considered an error to complete the address phase of the transfer and not have data available in the transmit FIFO buffer.
3. Program the `FIFOCTL` register. Indicate if the transmit FIFO buffer interrupts should occur with each byte transmitted (8-bits) or with each two bytes transmitted (16-bits).
4. Program the `IMSK` register. Enable bits associated with the desired interrupt sources. As an example, programming the value `0x0030` results in an interrupt output to the processor in the event that the master transfer completes, and the master transfer has an error.
5. Program the `MSTRCTL` register. This prepares and enables master mode operation. As an example, programming the value `0x0201` enables master mode operation, generates a 7-bit address, sets the direction to master-transmit, uses standard mode timing, and transmits 8 data bytes before generating a Stop condition.

*RESULT:*

**Table 20-4:** Master Mode Transmit Setup Interaction

| TWI Controller                                              | Processor                                                             |
|-------------------------------------------------------------|-----------------------------------------------------------------------|
| Interrupt: <code>XMTSERV</code> – Transmit buffer is empty. | Acknowledge: Clear interrupt source bits. Write transmit FIFO buffer. |

**Table 20-4:** Master Mode Transmit Setup Interaction (Continued)

| TWI Controller                               | Processor                                 |
|----------------------------------------------|-------------------------------------------|
| ...                                          | ...                                       |
| Interrupt: MCOMP – Master transfer complete. | Acknowledge: Clear interrupt source bits. |

## Master Mode Receive

Follow these programming steps for a single master mode receive.

1. Program the MSTRADDR register. This defines the address transmitted during the address phase of the transfer.
2. Program the FIFOCTL register. Indicate if receive FIFO buffer interrupts should occur with each byte received (8-bits) or with each two bytes received (16-bits).
3. Program the IMSK register. Enable bits associated with the desired interrupt sources. For example, programming the value 0x0030 results in an interrupt output to the processor in the event that the master transfer completes, and the master transfer has an error.
4. Program the MSTRCTL register. This prepares and enables master mode operation. As an example, programming the value 0x0205 enables master mode operation, generates a 7-bit address, sets the direction to master-receive, uses standard mode timing, and receives 8 data bytes before generating a Stop condition.

### RESULT:

The following table shows what the interaction between the TWI controller and the processor might look like using this example.

**Table 20-5:** Master Mode Receive Setup Interaction

| TWI Controller                               | Processor                                                           |
|----------------------------------------------|---------------------------------------------------------------------|
| Interrupt: RCVSERV – Receive buffer is full. | Acknowledge: Clear interrupt source bits. Read receive FIFO buffer. |
| ...                                          | ...                                                                 |
| Interrupt: MCOMP – Master transfer complete. | Acknowledge: Clear interrupt source bits. Read receive FIFO buffer. |

## Master Mode Program Flow

The following figure shows the program for the TWI in master mode.

Figure 20-10: Master Mode Program Flow

## TWI Register Descriptions

2-Wire Interface (TWI) contains the following registers.

**Table 20-6:** TWI Module Registers

| Name         | Description                   |
|--------------|-------------------------------|
| TWI_CLKDIV   | SCL Clock Divider Register    |
| TWI_CTL      | Control Register              |
| TWI_SLVCTL   | Slave Mode Control Register   |
| TWI_SLVSTAT  | Slave Mode Status Register    |
| TWI_SLVADDR  | Slave Mode Address Register   |
| TWI_MSTRCTL  | Master Mode Control Registers |
| TWI_MSTRSTAT | Master Mode Status Register   |
| TWI_MSTRADDR | Master Mode Address Register  |
| TWI_ISTAT    | Interrupt Status Register     |
| TWI_IMSK     | Interrupt Mask Register       |
| TWI_FIFOCTL  | FIFO Control Register         |
| TWI_FIFOSTAT | FIFO Status Register          |
| TWI_TXDATA8  | Tx Data Single-Byte Register  |
| TWI_TXDATA16 | Tx Data Double-Byte Register  |
| TWI_RXDATA8  | Rx Data Single-Byte Register  |
| TWI_RXDATA16 | Rx Data Double-Byte Register  |

## SCL Clock Divider Register

During master mode operation, the TWI\_CLKDIV holds values, which the TWI uses to create the high and low durations of the serial clock (SCL). The clock signal SCL is an output in master mode and an input in slave mode. The values in the TWI\_CLKDIV.CLKLO and TWI\_CLKDIV.CLKHI fields add up to the CLKDIV value the following equation.

$$\text{CLKDIV} = \text{TWI SCL period} / 10 \text{ MHz time reference}$$

Serial clock frequencies can vary from 400 KHz to less than 20 KHz. The resolution of the clock generated is 1/10 MHz or 100 ns. For example, for an SCL of 400 KHz (period = 1/400 KHz = 2500 ns) and an internal time reference of 10 MHz (period = 100 ns):

$$\text{CLKDIV} = 2500 \text{ ns} / 100 \text{ ns} = 25$$

For an SCL with a 30% duty cycle, use `TWI_CLKDIV.CLKLO = 17` and `TWI_CLKDIV.CLKHI = 8`.

**TWI\_CLKDIV: SCL Clock Divider Register - R/W**

Reset = 0x0000

**Figure 20-11:** TWI\_CLKDIV Register Diagram

**Table 20-7:** TWI\_CLKDIV Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                         |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:8    | CLKHI    | SCL Clock High Periods.<br>The <code>TWI_CLKDIV.CLKHI</code> specifies the number of 10 MHz time reference periods the serial clock (SCL) waits before a new clock low period begins, assuming a single master. |
| 7:0     | CLKLO    | SCL Clock Low Periods.<br>The <code>TWI_CLKDIV.CLKLO</code> specifies the number of internal time reference periods the serial clock (SCL) is held low.                                                         |

## Control Register

The `TWI_CTL` enables the TWI, establishes a relationship between the system clock (SCLK) and the TWI controller's internally timed events, and enables SCCB compatibility.

**TWI\_CTL: Control Register - R/W**

Reset = 0x0000

**Table 20-8:** TWI\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                      |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9       | SCCB     | SCCB Compatibility.<br>The <code>TWI_CTL.SCCB</code> enables SCCB compatible operation for the TWI. SCCB compatibility is an optional feature and should not be used in an I <sup>2</sup> C bus system. When this feature is enabled, all slave asserted acknowledgement bits are ignored by this master. This feature is valid only during transfers where the TWI is mastering an SCCB bus. Slave mode transfers should be avoided when this feature is enabled because the TWI controller always generates an acknowledge in slave mode.     |                                                                                                                                                      |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Disable SCCB compatibility<br>When disabled, Master transfers are not SCCB compatible.                                                               |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Enable SCCB compatibility<br>When enabled, Master transfers are SCCB compatible. All slave-asserted acknowledgement bits are ignored by this master. |
| 7       | EN       | Enable Module.<br>The <code>TWI_CTL.EN</code> enables TWI controller operation for either master and/or slave mode of operation. It is recommended that this bit be set at the time <code>TWI_CTL.PRESCALE</code> is initialized and remain set. This method guarantees accurate operation of bus busy detection logic.                                                                                                                                                                                                                         |                                                                                                                                                      |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Disable                                                                                                                                              |

| 6:0     | PRESCALE | SCLK Prescale Value.<br>The <code>TWI_CTL.PRESCALE</code> holds the pre-scaled value for the TWI internal time reference. This reference is derived from SCLK according to the formula:<br>$TWI\_CTL.PRESCALE = f_{SCLK}/10MHz$<br>The <code>TWI_CTL.PRESCALE</code> specifies the number of system clock (SCLK) periods used in the generation of one internal time reference. The value of <code>TWI_CTL.PRESCALE</code> must be set to create an internal time reference with a period of 10 MHz. It is represented as a 7-bit binary value. |                                                                                                                                                      |

## Slave Mode Control Register

The `TWI_SLVCTL` controls the logic associated with slave mode operation. Settings in this register do not affect master mode operation and should not be modified to control master mode functionality.

**TWI\_SLVCTL: Slave Mode Control Register - R/W**

Reset = 0x0000

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2       | TDVAL    | Transmit Data Valid for Slave.<br>The TWI_SLVCTL.TDVAL selects whether the data in the transmit FIFO is available (valid) for slave transmission (TWI_SLVCTL.TDVAL set). If the FIFO data is not available (invalid) for slave transmission (TWI_SLVCTL.TDVAL cleared), the data in the transmit FIFO is for master mode transmits, and the data is not allowed to be used during a slave transmit; the transmit FIFO is treated as if it is empty. |
|         |          | 0 Data Invalid for Slave Tx                                                                                                                                                                                                                                                                                                                                                                                                                         |
|         |          | 1 Data Valid for Slave Tx                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 0       | EN       | Enable Slave Mode.<br>The TWI_SLVCTL.EN enables slave operation. Enabling slave and master modes of operation concurrently is allowed. If disabled, no attempt is made to identify a valid address. If TWI_SLVCTL.EN is cleared during a valid transfer, clock stretching ceases, the serial data line is released, and the current byte is not acknowledged.                                                                                       |
|         |          | 0 Disable                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|         |          | 1 Enable                                                                                                                                                                                                                                                                                                                                                                                                                                            |

Slave Mode Status Register

During and at the conclusion of register slave mode transfers, the TWI\_SLVSTAT holds information on the current transfer. Generally slave mode status bits are not associated with the generation of interrupts. Master mode operation does not affect slave mode status bits.

Figure 20-14: TWI\_SLVSTAT Register Diagram

**Table 20-10:** TWI\_SLVSTAT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                   |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1       | GCALL    | General Call.<br>The <code>TWI_SLVSTAT.GCALL</code> indicates whether or not--at the time of addressing--the address was determined to be a general call. This bit self clears if slave mode is disabled ( <code>TWI_SLVCTL.EN = 0</code> ).                              |
|         |          | 0                      Not a General Call Address                                                                                                                                                                                                                         |
|         |          | 1                      General Call Address                                                                                                                                                                                                                               |
| 0       | DIR      | Transfer Direction for Slave.<br>The <code>TWI_SLVSTAT.DIR</code> indicates whether--at the time of addressing--the transfer direction was determined to be slave transmit or receive. This bit self clears if slave mode is disabled ( <code>TWI_SLVCTL.EN = 0</code> ). |
|         |          | 0                      Slave Receive                                                                                                                                                                                                                                      |
|         |          | 1                      Slave Transmit                                                                                                                                                                                                                                     |

## Slave Mode Address Register

The `TWI_SLVADDR` holds the slave mode address, which is the valid address to which the slave-enabled TWI controller responds. The TWI controller compares this value with the received address during the addressing phase of a transfer.

**TWI\_SLVADDR: Slave Mode Address Register - R/W**

Reset = 0x0000

**Figure 20-15:** TWI\_SLVADDR Register Diagram

**Table 20-11:** TWI\_SLVADDR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 6:0     | ADDR     | Slave Mode Address.     |

Master Mode Control Registers

The TWI\_MSTRCTL controls the logic associated with master mode operation. Bits in this register do not affect slave mode operation and should not be modified to control slave mode functionality.

| 14      | SDAOVR   | Serial Data Override.<br>The TWI_MSTRCTL.SDAOVR provides direct control of the serial data line when required. Normal master and slave mode operation should not require override operation. When TWI_MSTRCTL.SDAOVR is set, the TWI overrides normal serial data operation under the control of the transmit shift register and acknowledge logic, driving serial data output to an active 0 level and overriding all other logic. This state is held until this bit is cleared. When TWI_MSTRCTL.SDAOVR is cleared, the TWI permits normal serial data operation.                                                     |
|         |          | 0 Permit Normal SDA Operation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|         |          | 1 Override Normal SDA Operation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 13:6    | DCNT     | Data Transfer Count.<br>The TWI_MSTRCTL.DCNT indicates the number of data bytes to transfer. As each data word is transferred, the TWI decrements this counter. When TWI_MSTRCTL.DCNT decrements to 0, a stop condition is generated. Setting TWI_MSTRCTL.DCNT to 0xFF disables the counter. In this transfer mode, data continues to be transferred until it is concluded by setting the TWI_MSTRCTL.STOP bit. In the event a master transmit is aborted due to a slave data NAK, the value of TWI_MSTRCTL.DCNT equals the number of bytes not sent. The byte which was NAK'ed by the slave is counted as a sent byte. |
| 5       | RSTART   | Repeat Start.<br>The TWI_MSTRCTL.RSTART enables the TWI to issue a repeat start condition at the conclusion of the current transfer (TWI_MSTRCTL.DCNT = 0) and begin the next transfer. The current transfer concludes with updates to the appropriate status and interrupt bits. If errors occurred during the previous transfer, a repeat start does not occur. In the absence of any errors, master enable (TWI_MSTRCTL.EN) does not self clear on a repeat start.                                                                                                                                                   |
|         |          | 0 Disable Repeat Start                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|         |          | 1 Enable Repeat Start                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Table 20-12:** TWI\_MSTRCTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4       | STOP     | Issue Stop Condition.<br>The <code>TWI_MSTRCTL.STOP</code> directs the TWI to issue a stop condition. The transfer concludes as soon as possible avoiding any error conditions (as if data transfer count had been reached). At that time, the <code>TWI_IMSK</code> is updated along with any associated status bits.                                                                                                                                                                            |

## Master Mode Status Register

The `TWI_MSTRSTAT` holds information during master mode transfers and at their conclusion. Generally, master mode status bits are not directly associated with the generation of interrupts, but these bits offer information on the current transfer. Slave mode operation does not affect master mode status bits.

Note that while `TWI_MSTRSTAT.SCLSEN` is set (this condition could be due to having no pull-up resistor on `TWI_SCL` or another agent is driving `TWI_SCL` low), the acknowledge bits (`TWI_MSTRSTAT.ANAK` and `TWI_MSTRSTAT.DNAK`) do not update. This result occurs because the acknowledge conditions are sampled during the high phase of `TWI_SCL`.

**TWI\_MSTRSTAT: Master Mode Status Register - R/NW**

Reset = 0x0000

|         |          | 1                                                                                                                                                                                                                                                                                                                                                                 | SCL Active "Zero"<br>An active "zero" is being sensed on the serial clock. The source of the active driver is not known and can be internal or external. |

**Table 20-13:** TWI\_MSTRSTAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                 |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6       | SDASEN   | Serial Data Sense.<br>The TWI_MSTRSTAT.SDASEN indicates the active or inactive status of the serial data. Use this status bit when direct sensing of the serial data line is required. The register value is delayed due to the input filter (nominally 50 ns). Normal master and slave mode operation should not require this feature. |
|         |          | 0<br>SDA Inactive "One"<br>An inactive "one" is currently being sensed on the serial data line.                                                                                                                                                                                                                                         |
|         |          | 1<br>SDA Active "Zero"<br>An active "zero" is currently being sensed on the serial data line. The source of the active driver is not known and can be internal or external.                                                                                                                                                             |
| 5       | BUFWRERR | Buffer Write Error.<br>The TWI_MSTRSTAT.BUFWRERR indicates whether the current master transfer was aborted due to a receive buffer write error. The receive buffer and receive shift register were both full at the same time. This bit is W1C.                                                                                         |
|         |          | 0<br>No Status                                                                                                                                                                                                                                                                                                                          |
|         |          | 1<br>Buffer Write Error                                                                                                                                                                                                                                                                                                                 |
| 4       | BUFRDERR | Buffer Read Error.<br>The TWI_MSTRSTAT.BUFRDERR indicates whether the current master transfer was aborted due to the detection of a NAK during data transmission. This bit is W1C.                                                                                                                                                      |
|         |          | 0<br>No Status                                                                                                                                                                                                                                                                                                                          |
|         |          | 1<br>Buffer Read Error                                                                                                                                                                                                                                                                                                                  |

| 1       | LOSTARB  | Lost Arbitration.<br>The <code>TWI_MSTRSTAT.LOSTARB</code> indicates whether the current transfer was aborted due to the loss of arbitration with another master. This bit is W1C.                                                                                                                                         |
|         |          | 0                      No Status                                                                                                                                                                                                                                                                                           |
|         |          | 1                      Lost Arbitration                                                                                                                                                                                                                                                                                    |
| 0       | MPROG    | Master Transfer in Progress.<br>The <code>TWI_MSTRSTAT.MPROG</code> indicates whether or not a master transfer is in progress. If clear ( <code>TWI_MSTRSTAT.MPROG = 0</code> ), currently no transfer is taking place. This can occur after a transfer is complete or while an enabled master is waiting for an idle bus. |
|         |          | 0                      No Status                                                                                                                                                                                                                                                                                           |
|         |          | 1                      Master Transfer in Progress                                                                                                                                                                                                                                                                         |

## Master Mode Address Register

During the addressing phase of a transfer, the TWI controller, with its master enabled, transmits the contents of `TWI_MSTRADDR`. When programming this register, omit the read/write bit. That is, only the upper 7 bits that make up the slave address should be written to this register. For example, if the slave

address is b#1010000X, where X is the read/write bit, the TWI\_MSTRADDR is programmed with b#1010000, which corresponds to 0x50. When sending out the address on the bus, the TWI controller appends the read/write bit as appropriate based on the state of the TWI\_MSTRCTL.DIR bit.

**TWI\_MSTRADDR: Master Mode Address Register - R/W**

Reset = 0x0000

**Figure 20-18:** TWI\_MSTRADDR Register Diagram

**Table 20-14:** TWI\_MSTRADDR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 6:0     | ADDR     | Master Mode Address.    |

## Interrupt Status Register

The TWI\_ISTAT contains information about functional areas requiring servicing. Many of the bits serve as an indicator to further read and service various status registers. After servicing the interrupt source associated with a bit, the user must clear that interrupt source bit by writing a 1 to it.

**TWI\_ISTAT: Interrupt Status Register - R/WA**

Reset = 0x0000

**Figure 20-19:** TWI\_ISTAT Register Diagram

**Table 20-15:** TWI\_ISTAT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                               |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15      | SCLI     | Serial Clock Interrupt.<br>If the TWI is enabled (TWI_CTL.EN), SCLI is set on a high-to-low transition of the serial clock pin (SCLx). Normally, this bit is not required for I <sup>2</sup> C bus transfers. It will be initially set on an I <sup>2</sup> C transfer and does not require clearing. |
|         |          | 0<br>No Interrupt<br>No transition was detected on the SCLx pin.                                                                                                                                                                                                                                      |
|         |          | 1<br>Interrupt Detected<br>A high-to-low transition was detected on the SCLx pin. This bit is W1C.                                                                                                                                                                                                    |
| 14      | SDAI     | Serial Data Interrupt.<br>If the TWI is enabled (TWI_CTL.EN), SDAI is set on a high-to-low transition of the serial data pin (SDAx). Normally, this bit is not required for I <sup>2</sup> C bus transfers. It will be initially set on an I <sup>2</sup> C transfer and does not require clearing.   |
|         |          | 0<br>No Interrupt<br>No transition was detected on the SDAx pin.                                                                                                                                                                                                                                      |

|         |          | 1 Interrupt Detected<br>The slave has detected an address match, and a transfer has been initiated.                                                                                       |

## Interrupt Mask Register

The `TWI_IMSK` enables interrupt sources to assert the interrupt output. Each mask bit corresponds with one interrupt source bit in `TWI_ISTAT`. Reading and writing `TWI_IMSK` does not affect the contents of the `TWI_ISTAT`.

**TWI\_IMSK: Interrupt Mask Register - R/W**

Reset = 0x0000

**Figure 20-20:** TWI\_IMSK Register Diagram

**Table 20-16:** TWI\_IMSK Register Fields

| Bit No. | Bit Name | Description/Enumeration         |
|---------|----------|---------------------------------|
| 15      | SCLI     | Serial Clock Interrupt Mask.    |
|         |          | 0 Mask (Disable) Interrupt      |
|         |          | 1 Unmask (Enable) Interrupt     |
| 14      | SDAI     | Serial Data Interrupt Mask.     |
|         |          | 0 Mask (Disable) Interrupt      |
|         |          | 1 Unmask (Enable) Interrupt     |
| 7       | RXSERV   | Rx FIFO Service Interrupt Mask. |
|         |          | 0 Mask (Disable) Interrupt      |
|         |          | 1 Unmask (Enable) Interrupt     |
| 6       | TXSERV   | Tx FIFO Service Interrupt Mask. |
|         |          | 0 Mask (Disable) Interrupt      |
|         |          | 1 Unmask (Enable) Interrupt     |

|         |          | 0                                        | Mask (Disable) Interrupt  |
|         |          | 1                                        | Unmask (Enable) Interrupt |
| 0       | SINIT    | Slave Transfer Initiated Interrupt Mask. |                           |
|         |          | 0                                        | Mask (Disable) Interrupt  |
|         |          | 1                                        | Unmask (Enable) Interrupt |

## FIFO Control Register

The `TWI_FIFCTL` control bits affect only the FIFO and are not tied in any way with master or slave mode operation.

**TWI\_FIFCTL: FIFO Control Register - R/W**

Reset = 0x0000

**Figure 20-21:** TWI\_FIFCTL Register Diagram

FIFO Status Register

The TWI\_FIFOSTAT fields indicate the state of the FIFO buffers' receive and transmit contents. The FIFO buffers do not discriminate between master data and slave data. By using the status and control bits provided, the FIFO can be managed to allow simultaneous master and slave operation.

TWI\_FIFOSTAT: FIFO Status Register - R/NW

Reset = 0x0000

|         |          | 3                                                                                                                                                                                                                                                                                                       | Full<br>The FIFO is full and contains two bytes of data.                                                                        |

## Tx Data Single-Byte Register

The `TWI_TXDATA8` holds an 8-bit data value written into the FIFO buffer. Transmit data is entered into the corresponding transmit buffer in a first-in first-out order. For 16-bit peripheral bus writes, a write access to `TWI_TXDATA8` adds only one transmit data byte to the FIFO buffer. With each access, the transmit status (`TWI_FIFOSTAT.TXSTAT`) field is updated. If an access is performed while the FIFO buffer is full, the write is ignored and the existing FIFO buffer data and its status remains unchanged.

Figure 20-23: TWI\_TXDATA8 Register Diagram

Table 20-19: TWI\_TXDATA8 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 7:0     | VALUE    | Tx Data 8-Bit Value.    |

## Tx Data Double-Byte Register

The `TWI_TXDATA16` holds a 16-bit data value written into the FIFO buffer. To reduce interrupt output rates and peripheral bus access times, a double byte transfer data access can be done. Two data bytes can be written, effectively filling the transmit FIFO buffer with a single access.

The data is written in little endian byte order, where byte 0 is the first byte to be transferred and byte 1 is the second byte to be transferred. With each access, the transmit status (`TWI_FIFOSTAT.TXSTAT`) field is updated. If an access is performed while the FIFO buffer is not empty, the write is ignored and the existing FIFO buffer data and its status remains unchanged.

Figure 20-24: TWI\_TXDATA16 Register Diagram

**Table 20-20:** TWI\_TXDATA16 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 15:0    | VALUE    | Tx Data 16-Bit Value.   |

## Rx Data Single-Byte Register

The `TWI_RXDATA8` holds an 8-bit data value read from the FIFO buffer. Receive data is read from the corresponding receive buffer in a first-in first-out order. Although peripheral bus reads are 16 bits, a read access to `TWI_RXDATA8` accesses only one transmit data byte from the FIFO buffer. With each access, the receive status (`TWI_FIFOSTAT.RXSTAT`) field is updated. If an access is performed while the FIFO buffer is empty, the data is unknown and the FIFO buffer status remains indicating it is empty.

**TWI\_RXDATA8: Rx Data Single-Byte Register - RE/W**

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 7:0     | VALUE    | Rx Data 8-Bit Value.    |

## Rx Data Double-Byte Register

The `TWI_RXDATA16` holds a 16-bit data value read from the FIFO buffer. To reduce interrupt output rates and peripheral bus access times, a double byte receive data access can be performed. Two data bytes can be read, effectively emptying the receive FIFO buffer with a single access.

The data is read in little endian byte order, where byte 0 is the first byte received and byte 1 is the second byte received. With each access, the receive status (`TWI_FIFOSTAT.RXSTAT`) field is updated to indicate it is empty. If an access is performed while the FIFO buffer is not full, the read data is unknown and the existing FIFO buffer data and its status remains unchanged.

# 21 Controller Area Network (CAN)

The processor includes a controller area network (CAN) module, which implements the CAN 2.0B (active) protocol. This protocol is an asynchronous communications protocol used in both industrial and automotive control systems. The CAN protocol is well suited for control applications due to its capability to communicate reliably over a network. This is because the protocol incorporates CRC checking, message error tracking, and fault node confinement.

**NOTE:** This document assumes reader familiarity with the CAN standard. For more information, refer to Version 2.0 of the CAN Specification from Robert Bosch GmbH.

## CAN Features

The processor features one CAN module.

Key features of the CAN module include:

- Conformity to the CAN 2.0B (active) standard
- Dedicated acceptance mask for each mailbox
- Support for data rates of up to 1Mbit/s
- Support for standard (11-bit) and extended (29-bit) identifiers
- 32 mailboxes (8 transmit, 8 receive, 16 configurable)
- Data filtering (first 2 bytes) can be used for acceptance filtering (DeviceNet™ mode)
- Error status and warning registers
- Universal counter module
- Readable receive and transmit pin values
- Support for remote frames
- Active or passive network support
- Interrupts, including TX/RX complete, Error, and Global
- Clock derived from SCLK through a programmable divider, eliminating the need for an additional crystal

## CAN Functional Description

Following is a discussion of the functional operation of the CAN module.

### CAN Register List

The controller area network (CAN) module implements the CAN 2.0B (active) protocol. This protocol is an asynchronous communications protocol used in both industrial and automotive control systems. A set of registers govern CAN operations. For more information on CAN functionality, see the CAN register descriptions.

**Table 21-1:** CAN Module Registers

| Name       | Description                                              |
|------------|----------------------------------------------------------|
| CAN_MC1    | Mailbox Configuration 1 Register                         |
| CAN_MD1    | Mailbox Direction 1 Register                             |
| CAN_TRS1   | Transmission Request Set 1 Register                      |
| CAN_TRR1   | Transmission Request Reset 1 Register                    |
| CAN_TA1    | Transmission Acknowledge 1 Register                      |
| CAN_AA1    | Abort Acknowledge 1 Register                             |
| CAN_RMP1   | Receive Message Pending 1 Register                       |
| CAN_RML1   | Receive Message Lost 1 Register                          |
| CAN_MBTIF1 | Mailbox Transmit Interrupt Flag 1 Register               |
| CAN_MBRIF1 | Mailbox Receive Interrupt Flag 1 Register                |
| CAN_MBIM1  | Mailbox Interrupt Mask 1 Register                        |
| CAN_RFH1   | Remote Frame Handling 1 Register                         |
| CAN_OPSS1  | Overwrite Protection/Single Shot Transmission 1 Register |
| CAN_MC2    | Mailbox Configuration 2 Register                         |
| CAN_MD2    | Mailbox Direction 2 Register                             |
| CAN_TRS2   | Transmission Request Set 2 Register                      |

**Table 21-1:** CAN Module Registers (Continued)

| Name       | Description                                              |
|------------|----------------------------------------------------------|
| CAN_TRR2   | Transmission Request Reset 2 Register                    |
| CAN_TA2    | Transmission Acknowledge 2 Register                      |
| CAN_AA2    | Abort Acknowledge 2 Register                             |
| CAN_RMP2   | Receive Message Pending 2 Register                       |
| CAN_RML2   | Receive Message Lost 2 Register                          |
| CAN_MBTIF2 | Mailbox Transmit Interrupt Flag 2 Register               |
| CAN_MBRIF2 | Mailbox Receive Interrupt Flag 2 Register                |
| CAN_MBIM2  | Mailbox Interrupt Mask 2 Register                        |
| CAN_RFH2   | Remote Frame Handling 2 Register                         |
| CAN_OPSS2  | Overwrite Protection/Single Shot Transmission 2 Register |
| CAN_CLK    | Clock Register                                           |
| CAN_TIMING | Timing Register                                          |
| CAN_DBG    | Debug Register                                           |
| CAN_STAT   | Status Register                                          |
| CAN_CEC    | Error Counter Register                                   |
| CAN_GIS    | Global CAN Interrupt Status Register                     |
| CAN_GIM    | Global CAN Interrupt Mask Register                       |
| CAN_GIF    | Global CAN Interrupt Flag Register                       |
| CAN_CTL    | CAN Master Control Register                              |
| CAN_INT    | Interrupt Pending Register                               |
| CAN_MBTD   | Temporary Mailbox Disable Register                       |
| CAN_EWR    | Error Counter Warning Level Register                     |

**Table 21-1:** CAN Module Registers (Continued)

| Name               | Description                                   |
|--------------------|-----------------------------------------------|
| CAN_ESR            | Error Status Register                         |
| CAN_UCCNT          | Universal Counter Register                    |
| CAN_UCRC           | Universal Counter Reload/Capture Register     |
| CAN_UCCNF          | Universal Counter Configuration Mode Register |
| CAN_AMnnL          | Acceptance Mask (L) Register                  |
| CAN_AMnnH          | Acceptance Mask (H) Register                  |
| CAN_MBnn_DATA0     | Mailbox Word 0 Register                       |
| CAN_MBnn_DATA1     | Mailbox Word 1 Register                       |
| CAN_MBnn_DATA2     | Mailbox Word 2 Register                       |
| CAN_MBnn_DATA3     | Mailbox Word 3 Register                       |
| CAN_MBnn_LENGTH    | Mailbox Length Register                       |
| CAN_MBnn_TIMESTAMP | Mailbox Timestamp Register                    |
| CAN_MBnn_ID0       | Mailbox ID 0 Register                         |
| CAN_MBnn_ID1       | Mailbox ID 1 Register                         |

## ADSP-BF60x CAN Interrupt List

**Table 21-2:** ADSP-BF60x CAN Interrupt List

| Description   | ID | DMA Channel | Sensitivity |
|---------------|----|-------------|-------------|
| CAN0 Receive  | 40 |             | LEVEL       |
| CAN0 Transmit | 41 |             | LEVEL       |
| CAN0 Status   | 42 |             | LEVEL       |

## CAN External Interface

The interface to the CAN bus is a simple two-wire line. See the figures below for a symbolic representation of the CAN transceiver interconnection, as well as for a representative block diagram. Typically, the processor's CAN\_TX output and CAN\_RX input pins are connected to an external CAN transceiver's TX and RX pins (respectively). The CAN\_TX and CAN\_RX pins operate with TTL levels and are appropriate for operation with CAN bus transceivers according to ISO/DIS 11898.

**Figure 21-1:** Representation of CAN Transceiver Interconnection

CAN data is defined to be either dominant (logic 0) or recessive (logic 1). The default state of the CAN\_TX output is recessive.

## ADSP-BF60x Specific External Interface

The CAN\_TX and CAN\_RX signals can be found on GPIO Port G, pins PG1 and PG4 respectively. By default, these pins are in GPIO mode. SPORT\_2A and the timer signals are also multiplexed on this pin. To enable CAN functionality, the appropriate bits must be set in the PORTG\_FER and PORTG\_MUX registers.

The PG4 pin (CAN\_RX input pin) is also internally routed to the alternate capture input TACI2 of GP timer 2. This way, GP timer 2 can be used to auto-detect or adjust the bit rate on the CAN bus.

**NOTE:** The CAN Pad does not support 5V operation.

## CAN Architectural Concepts

The full-CAN controller features 32 message buffers, which are called mailboxes. Eight mailboxes are dedicated for message transmission, eight are for reception, and 16 are programmable in direction.

The CAN module architecture is based around a 32-entry mailbox RAM. The mailbox is accessed sequentially by the CAN serial interface or the Blackfin core. Each mailbox consists of eight 16-bit control and data registers and two optional 16-bit acceptance mask registers, all of which must be configured before the mailbox itself is enabled.

Since the mailbox area is implemented as RAM, the reset values of these registers are undefined. The data is divided into fields, which includes a message identifier, a time stamp, a byte count, up to 8 bytes of data, and several control bits

|       |                                       |                     |
|-------|---------------------------------------|---------------------|
| WORD0 | BYTE 6   BYTE 7                       | CANx_MB00_DATA0     |
| WORD1 | BYTE 4   BYTE 5                       | CANx_MB00_DATA1     |
| WORD2 | BYTE 2   BYTE 3                       | CANx_MB00_DATA2     |
| WORD3 | BYTE 0   BYTE 1                       | CANx_MB00_DATA3     |
| WORD4 | DLC                                   | CANx_MB00_LENGTH    |
| WORD5 | TSV                                   | CANx_MB00_TIMESTAMP |
| WORD6 | EXTID_HI / DFC                        | CANx_MB00_ID0       |
| WORD7 | AME   RTR   IDE   BASEID   EXTID_LO   | CANx_MB00_ID1       |
| WORD8 | EXTID_HI / DFC                        | CANx_AM00L          |
| WORD9 | FDF   FMD   AMIDE   BASEID   EXTID_LO | CANx_AM00H          |

The CAN Mailbox Identification (CAN\_MBxx\_ID0/1) register pair includes:

- The 29 bit Identifier (base part BASEID plus extended part EXTID\_LO/HI)
- The Acceptance Mask Enable bit (AME)
- The Remote Transmission Request bit (RTR)
- The Identifier Extension bit (IDE)

**NOTE:** Do not write to the Identifier of a message object while the mailbox is enabled for the CAN module (the corresponding bit in CAN\_MCx is set).

The other mailbox area registers are:

- The Data Length Code (DLC) in CAN\_MBxx\_LENGTH. The upper 12 bits of this register of each mailbox are marked as reserved. These 12 bits should always be set to 0.
- Up to eight bytes for the Data field, sent MSB first from the CAN\_MBxx\_DATA3/2/1/0 registers, respectively, based on the number of bytes defined in the DLC. For example, if only one byte is transmitted or received (DLC = 1), then it is stored in the most significant byte of the CAN\_MBxx\_DATA3 register.
- Two bytes for the Time Stamp Value (TSV) in the CAN\_MBxx\_TIMESTAMP register

The final registers in the mailbox area are the Acceptance Mask Registers (CAN\_AMxxH and CAN\_AMxxL). The Acceptance Mask is enabled when the AME bit is set in the CAN\_MBxx\_ID1 register.

The “filtering on data field” option can be enabled by setting DNM bit in the CAN Master Control register (CAN\_CTL) and FDF bit in the corresponding Acceptance Mask register (CAN\_AMxxH). When enabled, EXTID\_HI[15:0] bits of CAN\_MBxx\_ID0 are reused as Acceptance Code (DFC) for the Data Field Filtering.

## CAN Block Diagram

The following figure shows a block diagram of the CAN module.

CAN Controller Block Diagram

## CAN Mailbox Control

Mailbox control MMRs function as control and status registers for the 32 mailboxes. Each bit in these registers represents one specific mailbox. Since CAN MMRs are all 16 bits wide, pairs of registers are required to manage certain functionality for all 32 individual mailboxes. Mailboxes 0-15 are configured/monitored in registers with a suffix of 1. Similarly, mailboxes 16-31 use the same named register with a suffix of 2. For example, the CAN mailbox direction registers (`CAN_MDx`) would control mailboxes as shown in the figure below.

**Figure 21-2: CAN Mailbox Register Pair**

The Mailbox Control Register area consists of these register pairs:

- CAN\_MC1 and CAN\_MC2 (Mailbox Enable registers)
- CAN\_MD1 and CAN\_MD2 (Mailbox Direction registers)
- CAN\_TA1 and CAN\_TA2 (Transmit Acknowledge registers)
- CAN\_AA1 and CAN\_AA2 (Abort Acknowledge registers)
- CAN\_TRS1 and CAN\_TRS2 (Transmit Request Set registers)
- CAN\_TRR1 and CAN\_TRR2 (Transmit Request Reset registers)
- CAN\_RMP1 and CAN\_RMP2 (Receive Message Pending registers)
- CAN\_RML1 and CAN\_RML2 (Receive Message Lost registers)
- CAN\_RFH1 and CAN\_RFH2 (Remote Frame Handling registers)
- CAN\_OPSS1 and CAN\_OPSS2 (Overwrite Protection/Single Shot transmission registers)
- CAN\_MBIM1 and CAN\_MBIM2 (Mailbox Interrupt Mask registers)
- CAN\_MBTIF1 and CAN\_MBTIF2 (Mailbox Transmit Interrupt Flag registers)
- CAN\_MBRIF1 and CAN\_MBRIF2 (Mailbox Receive Interrupt Flag registers)

Since mailboxes 24–31 support transmit operation only and mailboxes 0–7 are receive-only mailboxes, the lower eight bits in the ‘1’ registers and the upper eight bits in the ‘2’ registers are sometimes reserved or are restricted in their usage.

## CAN Protocol Fundamentals

Although the CAN\_RX and CAN\_TX pins are TTL-compliant signals, the CAN signals beyond the transceiver have asymmetric drivers. A low state on the CAN\_TX pin activates strong drivers while a high state is driven weakly. Consequently, active low is called the *Dominant* state and active high is the *Recessive* state. If the CAN module is passive, the CAN\_TX pin is always high. If two CAN nodes transmit at the same time, dominant bits overwrite recessive bits.

The CAN protocol defines that all nodes trying to send a message on the CAN bus attempt to send a frame once the CAN bus becomes available. The start of frame indicator (SOF) signals the beginning of a new frame. Each CAN node then begins transmitting its message starting with the message ID.

While transmitting, the CAN controller samples the CAN\_RX pin to verify that the logic level being driven is the value it just placed on the CAN\_TX pin. This is where the names for the logic levels apply. If a transmitting node places a recessive 1 on the CAN\_TX pin and detects a dominant 0 on the CAN\_RX pin, it knows that another node has placed a dominant bit on the bus, which means another node is a higher priority.

Therefore, if the value sensed on the CAN\_RX pin is the value driven on the CAN\_TX pin, transmission continues, otherwise the CAN controller senses that it has lost arbitration and module configuration determines the next course of action.

**Figure 21-3:** Standard CAN Frame

The figure above shows a basic 11-bit identifier frame. After the SOF and identifier is the RTR bit, which indicates whether the frame contains data (data frame) or is a request for data associated with the message identifier in the frame being sent (remote frame).

**NOTE:** In the CAN protocol, a dominant bit in the RTR field wins arbitration against a remote frame request (RTR = 1) for the same message ID, this allows a remote request to be a lower priority than a data frame.

The next field of interest is the IDE. When set, it indicates that the message is an extended frame with a 29-bit identifier instead of an 11-bit identifier. In an extended frame, the first part of the message resembles the figure below.

Therefore a dominant bit in the IDE field wins arbitration against an extended frame with the same lower 11-bits and standard frames are higher priority than extended frames.

**Figure 21-4:** Extended CAN Frame

The substitute remote request bit (SRR, always sent as recessive), the reserved bits r0 and r1 (always sent as dominant), and the checksum (CRC) are generated automatically by the internal logic.

## CAN Data Transfer Modes

The following sections provide a discussion of the data transfer modes supported by the CAN controller.

### CAN Transmit Operation

The figure below shows the CAN transmit operation. Mailboxes 24-31 are dedicated transmitters. Mailboxes 8-23 can be configured as transmitters by writing 0 to the corresponding bit in the `CAN_MDx` register. After writing the data and the identifier into the mailbox area, the message is sent after mailbox *n* is enabled (`CAN_MCx.MBn = 1`) and, subsequently, the corresponding Transmit Request bit is set (`CAN_TRSx.MBn = 1`).

When a transmission completes, the corresponding bits in the `CAN_TRSx` and `CAN_TRRx` registers are cleared. If transmission was successful, the corresponding bit in the `CAN_TAx` register is set. If the transmission was aborted due to lost arbitration or a CAN error, the corresponding bit in the `CAN_AAx` register is set. A requested transmission can also be manually aborted by setting the corresponding bit in the `CAN_TRRx` register.

Multiple `CAN_TRSx.MBn` bits can be set simultaneously by software, and these bits are reset after either a successful or an aborted transmission.

These bits are also set by the CAN hardware in the following cases:

- when using the Auto-Transmit mode of the universal counter,
- when a message loses arbitration and the Single-Shot `CAN_OPSSx.MBn` bit is not set, or
- in the event of a remote frame request.

The latter is only possible for receive/transmit mail-boxes if the Automatic Remote Frame Handling feature is enabled (`CAN_RFHx.MBn = 1`).

Special care should be given to mailbox area management when a `CAN_TRSx` bit is set. Write access to the mailbox is permissible with a bit set, but changing data in such a mailbox may lead to unexpected data during transmission.

Enabling and disabling mailboxes has an impact on transmit requests. Setting the `CAN_TRSx` bit associated with a disabled mailbox may result in erroneous behavior. Similarly, disabling a mailbox before the associated `CAN_TRSx` bit is reset by the internal logic can cause unpredictable results.

### Retransmission

Normally, the current message object is sent again after arbitration is lost or an error frame is detected on the CAN bus line. If there is more than one transmit message object pending, the message object with the highest mailbox is sent first (see figure below). The currently aborted transmission is restarted after any messages with higher priority are sent.

A message which is currently under preparation is not replaced by another message which is written into the mailbox. The message under preparation is one that is copied into the temporary transmit buffer when the internal transmit request for the CAN core module is set. The message in the buffer is not replaced until it is sent successfully, the arbitration on the CAN bus line is lost, or there is an error frame on the CAN bus line.

**Figure 21-5:** CAN Transmit Operation Flow Chart

### Single-Shot Transmission

If the Single Shot Transmission feature is used ( $CAN\_OPSSx.MBn = 1$ ), the corresponding  $CAN\_TRSx$  bit is cleared after the message is successfully sent or even if the transmission is aborted due to a lost arbitration or an error frame on the CAN bus line. Thus, there is no further attempt to transmit the message again if the initial try failed, and the Abort error is reported ( $CAN\_AAx.MBn = 1$ ).

### Auto-Transmission

In Auto-Transmit mode, the message in mailbox 11 (MB11) can be sent periodically using the universal counter. This mode is often used to broadcast heartbeats to all CAN nodes. Accordingly, messages sent this way usually have high priority.

The period value is written to the  $CAN\_UCRC$  register. The Auto-Transmission mode is enabled by setting the  $CAN\_UCCNF.UCCNF$  field to 0x03. When enabled, the counter  $CAN\_UCCNT$  is loaded with the value in the  $CAN\_UCRC$  register. The counter decrements at the CAN bit clock rate down to 0 and is then reloaded from  $CAN\_UCRC$ . Each time the counter reaches a value of 0, the  $CAN\_TRS1.MB11$  bit is automatically set by internal logic, and the corresponding message from mailbox 11 is sent.

For proper auto-transmit operation, mailbox 11 must be configured as a transmit mailbox and must contain valid data (identifier, control bits, and data) before the counter first expires after this mode is enabled.

**CAN Receive Operation**

The CAN hardware autonomously receives messages and discards invalid messages. Once a valid message is successfully received, the receive logic interrogates all enabled receive mailboxes sequentially, from mailbox 23 down to mailbox 0, whether the message is of interest to the local node or not.

Each incoming data frame is compared to all identifiers stored in active receive mailboxes (respective mailbox indices of CAN\_MD and CAN\_MC registers set to 1) and to all active transmit mailboxes with the Remote Frame Handling feature enabled (CAN\_RFHx.MBn = 1). The Message Identifier of the received message, along with the Identifier Extension (CAN\_MBxx\_ID1.IDE) and Remote Transmission Request (CAN\_MBxx\_ID1.RTR) bits, are compared against each mailbox’s register settings. In Standard mode, the message is compared to the content of the CAN\_MByy\_ID1 register. In extended mode, the content of the CANx\_MByy\_ID0 register must also match.

If the Acceptance Mask Enable (AME) bit in the CAN\_MByy\_ID1 register is not set, a match is signaled only if IDE, RTR, and all (11 or 29) identifier bits are exact. If, however, the AME is set, the Acceptance Mask Registers (CAN\_AMxxH/L) determine which of the IDE and RTR bits need to match.

The following logic applies:

$$[(\text{Received Message ID}) \text{ XNOR } (\text{CAN\_MBxx\_ID0/1})] \text{ OR } [(\text{AME}) \text{ AND } (\text{CAN\_AMxxH/L})].$$

This logic appears graphically in the figure below.

**Figure 21-6:** CAN Message Receive Logic

A one (1) at the respective bit position in the CAN\_AMxxH/L Mask registers means that the bit does not need to match when AME=1. This way, a mailbox can accept a group of messages.

**Table 21-3:** Mailbox Used for Acceptance Filtering

| MCn | MDn | RFHn | Mailbox n | Comment            |
|-----|-----|------|-----------|--------------------|
| 0   | x   | x    | Ignored   | Mailbox n disabled |

**Table 21-3:** Mailbox Used for Acceptance Filtering (Continued)

| MCn | MDn | RFHn | Mailbox n | Comment                                                                              |
|-----|-----|------|-----------|--------------------------------------------------------------------------------------|
| 1   | 0   | 0    | Ignored   | Mailbox n enabled, Mailbox n configured for transmit, Remote frame handling disabled |
| 1   | 0   | 1    | Used      | Mailbox n enabled, Mailbox n configured for transmit, Remote frame handling enabled  |
| 1   | 1   | x    | Used      | Mailbox n enabled, Mailbox n configured for receive                                  |

If the acceptance filter finds a matching identifier, the content of the received data frame is stored in that mailbox. A received message is stored only once, even if multiple receive mailboxes match its identifier. If the current identifier does not match any mailbox, the message is not stored.

The figure below illustrates the decision tree of the receive logic when processing the individual mailboxes.

If a message is received for a mailbox and that mailbox still contains unread data ( $RMP_n = 1$  in the Receive Message Pending register), then the user has to decide whether the old message should be overwritten or not. If the `CAN_OPSSx.OPSSn` bit is cleared, the corresponding `CAN_RMLx.RMLn` bit is set, and the stored message is overwritten. This results in the Receive Message Lost interrupt being raised (`CAN_GIS.RMLIS` is set). If, however, the `CAN_OPSSx.OPSSn` bit is set, the next mailboxes are checked for another matching identifier. If no match is found, the message is discarded, and the next message is checked.

*If a receive mailbox is disabled, an ongoing receive message for that mailbox is lost even if a second mailbox is configured to receive the same identifier.*

**Figure 21-7:** CAN Receive Operation Flow Chart

**CAN Data Acceptance Filtering**

If DeviceNet mode is enabled (`CAN_CTL.DNM = 1`) and the mailbox is set up for filtering on data field, the filtering is done on the standard ID of the message and data fields. The data field filtering can be programmed for either the first byte only or the first two bytes, as shown the table below.

If the `CAN_AMxxH.FDF` bit is set, the corresponding `CAN_AMxxL` register holds the Data Field Mask (DFM[15:0]). If the `FDF` bit is instead cleared, the corresponding `CAN_AMxxL` register holds the Extended Identifier Mask (EXTID\_HI[15:0]).

**Table 21-4:** Data Field Filtering

| FDF (Filter on Data Field) | FMD (Full Mask Data Field) | Description                              |
|----------------------------|----------------------------|------------------------------------------|
| 0                          | 0                          | Do not allow filtering on the data field |
| 0                          | 1                          | Not allowed. FMD must be 0 if FDF is 0   |

**Table 21-4:** Data Field Filtering (Continued)

| FDF (Filter on Data Field) | FMD (Full Mask Data Field) | Description                    |
|----------------------------|----------------------------|--------------------------------|
| 1                          | 0                          | Filter on first data byte only |
| 1                          | 1                          | Filter on first two data bytes |

## CAN Watchdog Mode

Watchdog mode is used to make sure that messages are received periodically. It is often used to observe whether or not a certain node on the network is alive and functioning properly, and, if not, to detect and manage its failure case accordingly.

This mode can be enabled by programming the Universal Counter to Watchdog mode by setting the `CAN_UCCNF.UCCNF[3:0]` to 0x2. Once enabled, the `CAN_UCCNT` register is loaded with the predefined value contained in `CAN_UCRC`. This counter then decrements at the CAN bit rate.

If the `CAN_UCCNF.UCCT` and `CAN_UCCNF.UCRC` bits are set and a message is received in mailbox 4 before the counter counts down to 0, the counter is reloaded with the `CAN_UCRC` contents. If the counter has counted down to 0 without receiving a message in mailbox 4, then the `CAN_GIS.UCEIS` bit is set, and the counter is automatically reloaded with the contents of the `CAN_UCRC` register. If an interrupt is desired for this event, the `CAN_GIM.UCEIM` bit must also be set. With the mask bit set, when a watchdog interrupt occurs, the `CAN_GIF.UCEIF` bit is also set.

The counter can be reloaded with the contents of `CAN_UCRC` or disabled by writing to the `CAN_UCCNF` register.

The time period it takes for the watchdog interrupt to occur is controlled by the value written into the `CAN_UCRC` register.

## CAN Time Stamps

To get an indication of the time of reception or the time of transmission for each message, program the CAN universal counter to Time Stamp Mode. This mode can be enabled by setting the `CAN_UCCNF.UCCNF[3:0]` field to 0x01.

If enabled, the value of the 16-bit free-running counter (`CAN_UCCNT`) is written into the `CAN_MBxx.TIMESTAMP` register of the corresponding mailbox when a received message is stored or a message is transmitted.

The Time Stamp Value is captured at the sample point of the Start Of Frame (SOF) bit of each incoming or outgoing message. Afterwards, this Time Stamp Value is copied to the `CAN_MBxx_TIMESTAMP` register of the corresponding mailbox.

If the mailbox is configured for Automatic Remote Frame Handling (`CAN_RFHx.RFHn = 1`), the Time Stamp Value is written for transmission of a Data frame (mailbox configured as transmit) or the reception of the requested Data frame (mailbox configured as receive).

The counter can be cleared by setting the `CAN_UCCNF.UCRC` bit to 1, or disabled by clearing the `CAN_UCCNF.UCE` bit. The counter can also be loaded with a value by writing to the counter register itself (`CAN_UCCNT`).

It is also possible to clear the counter (`CAN_UCCNT`) by reception of a message in mailbox number 4 (synchronization of all time stamp counters in the system). This is accomplished by setting the `CAN_UCCNF.UCCT` bit.

An overflow of the counter sets the `CAN_GIS.UCEIS` bit. A Global CAN Interrupt can optionally occur by unmasking the `CAN_GIM.UCEIM` bit. If the interrupt source is unmasked, the `CAN_GIF.UCEIF` bit is also set.

## **CAN Remote Frame Handling**

Automatic handling of remote frames can be enabled for a transmit mailbox by setting the corresponding `CAN_RFHx.RFHn` bit of a transmit mailbox.

Remote frames are Data frames with no data field and the RTR bit set. The Data Length Code (DLC) of the responding data frame is overruled by the DLC of the requesting Remote Frame. A DLC can be programmed with values in the range of 0 to 15, but DLC values greater than 8 are considered as 8.

A remote frame contains:

- the Identifier bits
- the control field DLC (Data Length Count)
- the Remote Transmission Request (RTR) bit

Only configurable mailboxes, MB8–MB23, can process remote frames, but all mailboxes can receive and transmit remote frame requests. When setup for Automatic Remote Frame Handling, the `CAN_OPSSx` register has no effect. All content of a mailbox is always overwritten by an incoming message.

*If a Remote frame is received, the DLC of the corresponding mailbox is overwritten with the received value.*

Erroneous behavior may result when the `RFHn` bit is changed while the corresponding mailbox is currently being processed. To avoid the risk of inconsistent messages, it is recommended to temporarily disable the mailbox while its Data registers are updated.

## CAN Mailbox Disabling (Temporary)

If a mailbox is enabled and configured as “transmit,” write accesses to the data field should be guarded to avoid transmission of inconsistent messages. Special care must be taken if the mailbox is transmitting (or attempting to transmit) repeatedly. Also, if this mailbox is used for Automatic Remote Frame Handling, the data field must be updated without losing an incoming Remote Request frame and without sending inconsistent data. Therefore, the CAN controller allows for temporary mailbox disabling, which can be enabled by programming the Mailbox Temporary Disable register (CAN\_MBTDR).

The pointer to the requested mailbox must be written to the CAN\_MBTDR.TDPTR[4:0] field, and the CAN\_MBTDR.TDR bit must be set. The corresponding CAN\_MBTDR.TDA flag is subsequently set by the internal logic.

If a mailbox is configured as “transmit” ( $MD_n = 0$ ) and TDA bit is set, the content of the Data Field of that mailbox can be updated. If there is an incoming remote Request Frame while the mailbox is temporarily disabled, the corresponding Transmit Request Set bit (TRS<sub>n</sub>) is set by the internal logic and the Data Length Code (DLC) of the incoming message is written to the corresponding mailbox. However, the message being requested is not sent until the CAN\_MBTDR.TDR bit is cleared. Similarly, all transmit requests for temporarily disabled mailboxes are ignored until the CAN\_MBTDR.TDR bit is cleared. Additionally, transmission of a message is immediately aborted if the mailbox is temporarily disabled and the corresponding Transmission Request Reset (TRR<sub>n</sub>) bit for this mailbox is set.

If a mailbox is configured as “receive” ( $MD_n = 1$ ), then after issuing a Temporary Disable Request, the CAN\_MBTDR.TDA flag is set, and the mailbox is not processed. If there is an incoming message for a mailbox being temporarily disabled, the internal logic waits until the reception is complete or there is an error on the CAN bus before setting CAN\_MBTDR.TDA. Once this flag is set, the mailbox can then be completely disabled ( $MC_n = 0$ ) without the risk of losing an incoming frame. The CAN\_MBTDR.TDR bit must then be reset as soon as possible.

When the CAN\_MBTDR.TDA flag is set for a given mailbox, only the Data field of that mailbox can be updated. Accesses to the Control bits and the Identifier are denied.

## CAN Operating Modes

The CAN controller is in configuration mode when coming out of processor reset or hibernate. It is only when the CAN is in configuration mode that hardware behavior can be altered. Before initializing the mailboxes themselves, the CAN bit timing must be set up to work on the CAN bus to which the controller is expected to connect.

## Bit Timing

The CAN controller does not have a dedicated clock. Instead, the CAN clock is derived from the system clock based on a configurable number of time quanta. The Time Quantum (TQ) is derived from the formula:

$$TQ = (BRP+1)/SCLK,$$

where BRP is the 10-bit Bit Rate Prescaler field in the CAN\_CLK register.

Although the BRP field can be set to any value, it is recommended that the value be greater than or equal to 4, as restrictions apply to the bit timing configuration when BRP is less than 4.

The CAN\_CLK register defines the TQ value, and multiple time quanta make up the duration of a CAN bit on the bus. The CAN\_TIMING register controls the nominal bit time and the sample point of the individual bits in the CAN protocol. The figure below shows the three phases of a CAN bit—the synchronization segment, the segment before the sample point, and the segment after the sample point.

**Figure 21-8:** Three Phases of a CAN Bit

The synchronization segment is fixed to one TQ. It is required to synchronize the nodes on the bus. All signal edges are expected to occur within this segment.

The TSEG1 and TSEG2 fields of the CAN\_TIMING register control how many TQs the CAN bits consist of, resulting in the CAN bit rate. The nominal bit time is given by the formula,  $t_{BIT} = TQ \times [1 + (1 + TSEG1) + (1 + TSEG2)]$

For safe receive operation on given physical networks, the sample point is programmable by the TSEG1 field. The TSEG2 field holds the number of TQs needed to complete the bit time. Often, best sample reliability is achieved with sample points in the high 80% range of the bit time. Never use sample points lower than 50%. Thus, TSEG1 should always be greater than or equal to TSEG2.

The CAN module does not distinguish between the Propagation Segment and the Phase Segment-1 as defined by the standard. The TSEG1 value is intended to cover both of them. The TSEG2 value represents the Phase Segment-2.

If the CAN module detects a recessive-to-dominant edge outside the synchronization segment, it can automatically move the sampling point such that the CAN bit is still handled properly. The Synchronization Jump Width (SJW) field specifies the maximum number of TQs, ranging from 1 to 4 (SJW + 1), allowed for such a re-synchronization attempt. The SJW value should not exceed TSEG2 or TSEG1. Therefore, the fundamental rule for writing CAN\_TIMING is:

$SJW \leq TSEG2 \leq TSEG1$

In addition to this fundamental rule, Phase Segment-2 must also be greater than or equal to the Information Processing Time (IPT). This is the time required by the logic to sample the CAN\_RX input, which is 3 system clock cycles.

Because of this, restrictions apply to the minimal value of TSEG2 if the Bit Clock Prescaler (BRP) is lower than 2. If BRP is set to 0, the TSEG2 field must be greater than or equal to 2. Else if the BRP is set to 1, the minimum TSEG2 is 1.

**NOTE:** All nodes on a CAN bus should use the same nominal bit rate.

With all the timing parameters set, the final consideration is how sampling is performed. The default behavior of the CAN controller is to sample the CAN bit once at the sampling point described by the CAN\_TIMING register, controlled by the SAM bit. If the SAM bit is set, however, the input signal is oversampled three times at the system clock rate. The resulting value is generated by a majority decision of the three sample values. Always keep the SAM bit cleared if the BRP value is less than 4.

Do not modify the CAN\_CLK or CAN\_TIMING registers during normal operation. Always enter configuration mode first. Writes to these registers have no effect if not in configuration or debug mode. If not coming out of processor reset or hibernate, enter configuration mode by setting the CAN\_CTL.CCR bit and poll the CAN\_STAT register until CAN\_STAT.CCA is set.

**NOTE:** If the CAN\_TIMING.TSEG1 field is programmed to 0, the module doesn't leave the configuration mode.

During configuration mode, the module is not active on the CAN bus line. The CAN\_TX output pin remains recessive and the module does not receive/transmit messages or error frames. After leaving the configuration mode, all CAN core internal registers and the CAN error counters are set to their initial values.

A soft reset does not change the values of CAN\_CLK and CAN\_TIMING. Thus, an ongoing transfer through the CAN bus cannot be corrupted by changing the bit timing parameter or initiating the soft reset (by setting the CAN\_CTL.SRS bit).

## CAN Low Power Features

The CAN module includes built-in Sleep and Suspend modes to save power. It also responds to the Hibernate power state on processors that support that state. The behavior of the CAN module in these modes is described in the following sections.

### CAN Built-In Suspend Mode

The most modest of power savings mode is the suspend mode. This mode is entered by setting the CAN\_CTL.CSR bit. The module enters the suspend mode after the current operation of the CAN bus is finished, at which point the internal logic sets the CAN\_STAT.CSA bit. Once this mode is entered, the module is no longer active on the CAN bus line, slightly reducing power consumption. The CAN\_TX output

pin remains at recessive state, and the module does not receive/transmit messages or error frames. The content of the CAN Error Counter register remains unchanged. The Suspend mode can subsequently be exited by clearing `CAN_CTL.CSR`. The only differences between Suspend mode and Configuration mode are that writes to the `CAN_CLK` and `CAN_TIMING` registers are still locked in suspend mode, and the `CAN_CTL` and `CAN_STAT` registers are not reset when exiting suspend mode.

## **CAN Built-In Sleep Mode**

The next level of power savings can be realized by using the CAN module's built-in sleep mode. This mode is entered by setting the `CAN_CTL.SMR` bit. The module enters the sleep mode after the current operation of the CAN bus is finished. Once this mode is entered, many of the internal CAN module clocks are shut off, reducing power consumption, and the `CAN_INT.SMACK` bit is set. When the CAN module is in sleep mode, all register reads return the contents of `CAN_INT` instead of the usual contents. All register writes, except to `CAN_INT`, are ignored in sleep mode. A small part of the module is clocked continuously to allow for wakeup out of sleep mode. A write to the `CAN_INTR` register ends sleep mode. If the `CAN_CTL.WBA` bit is set before entering sleep mode, a dominant bit on the `CAN_RX` pin also ends sleep mode. When software sets the `CAN_CTL.SMR` bit, hardware sets the `CAN_CTL.CSR` bit as well, making Sleep mode a superset of Suspend mode. When the controller wakes up from Sleep mode, hardware automatically clears `CAN_CTL.SMR` and `CAN_CTL.CSR`. If, however, the controller never enters sleep mode, because the wake-up condition was met before `CAN_INT.SMACK` bit turns to one, the `CAN_CTL.SMR` and `CAN_CTL.CSR` may not get cleared automatically. Therefore, it is good programming practice to always clear those two bits by software when returning from sleep mode.

## **CAN Wakeup From Hibernate State**

Many processors provide a hibernate state, where the internal voltage regulator shuts off the internal power supply to the chip, turning off the core and system clocks in the process. In this mode, the only power drawn is that used by the regulator circuitry awaiting any of the possible hibernate wakeup events. One such event is a wakeup due to CAN bus activity. After hibernation, the CAN module must be re-initialized. For low power designs, the external CAN bus transceiver is typically put into standby mode through one of the processor's general purpose I/O pins. While in standby mode, the CAN transceiver continually drives the recessive logic '1' level onto the `CAN_RX` pin. If the transceiver then senses CAN bus activity, it will, in turn, drive the `CAN_RX` pin to the dominant logic '0' level. This signals to the processor that CAN bus activity is detected. If the internal voltage regulator is programmed to recognize CAN bus activity as an event to exit hibernate state, the part responds appropriately. Otherwise, the activity on the `CAN_RX` pin has no effect on the processor state.

## **Soft Reset**

The CAN controller features a build-in reset mechanism which is referred to as Soft Reset. Soft reset is entered immediately after software has set `CAN_CTL.SRS` bit. Soft reset brings all control registers to a defined state. Mailbox and error registers remain unaffected. Soft reset does not alter the `CAN_TIMING` and `CAN_CLK` registers and does not disturb the on-going transmission of a currently pending message, acknowledge bit or error frame. However, when recovering from soft reset, software may lose track of transmission or reception reports and interrupts.

## CAN Event Control

The following is a description of how CAN events are generated and controlled.

### CAN Interrupt Signals

The CAN module provides three independent interrupts: two mailbox interrupts (Mailbox Receive Interrupt (MBRIRQ) and mailbox transmit interrupt (MBTIRQ) and a global CAN status interrupt (GIRQ). The values of these three interrupts can also be read back through the CAN\_GIS registers.

### Mailbox Interrupts

Each of the 32 mailboxes in the CAN module may generate a receive or transmit interrupt, depending on the mailbox configuration. To enable a mailbox to generate an interrupt, set the corresponding CAN\_MBIMn bit.

If a mailbox is configured as a receive mailbox, the corresponding CAN\_MBRIFn bit and CAN\_RMPn bit are set after a received message is stored in mailbox n. If the automatic remote frame handling feature is used (CAN\_RFHn = 1), the Receive Interrupt Flag is set after the requested data frame is stored in the mailbox.

If any CAN\_MBRIF bits are set, the MBRIRQ interrupt output is raised in CAN\_INTR. In order to clear the MBRIRQ interrupt request, all of the set MBRIFn bits must be cleared by software by writing a 1 to those set bit locations in CAN\_MBRIFn. Prior to this, the corresponding CAN\_RMPn bit must also be cleared by software.

If a mailbox is configured as a transmit mailbox, the corresponding CAN\_MBTIFn bit in the transmit interrupt flag is set after the message in mailbox n is sent correctly, and the corresponding CAN\_TAn bit also gets set. The TAn bits maintain state even after the corresponding mailbox n is disabled (MCn = 0). If the automatic remote frame handling feature is used, then transmit interrupt flag is set after the requested data frame is sent from the mailbox.

If any MB bits are set in CAN\_MBTIFn, the MBTIRQ interrupt output is raised in CAN\_INTR. In order to clear the MBTIRQ interrupt request, all of the set MBTIFn bits must be cleared by software by writing a 1 to those set bit locations in CAN\_MBTIFn. Additionally, software must clear the associated TAn bit or set the associated TRSn bit to clear the interrupt source that asserts the MBTIFn bit.

### Global CAN Interrupt

The global CAN interrupt logic is implemented with three registers:

- The CAN\_GIM register, where each interrupt source can be enabled or disabled separately
- The CAN\_GIS register
- The CAN\_GIF register

The interrupt mask bits only affect the content of the `CAN_GIF` register. If the mask bit is not set in the `CAN_GIM` register, the corresponding flag bit is not set when the event occurs. The interrupt status bits in the `CAN_GIS` register, however, are always set if the corresponding interrupt event occurs, independent of the mask bits. Thus, the interrupt status bits can be used for polling of interrupt events.

The `CAN_INTR.GIRQ` bit is only asserted if a bit in the `CAN_GIF` register is set. The read-only `GIRQ` bit remains set as long as at least one bit in `CAN_GIF` is set. All bits in the Interrupt Status and Interrupt Flag registers remain set until cleared by software or a soft reset has occurred.

*The `CAN_GIF` register is read-only (RO). In the Global CAN Interrupt ISR, the interrupt latch should be cleared by writing to 1 to the corresponding bit of the `CAN_GIS` register, which clears the related bits of the `CAN_GIS` and `CAN_GIF` registers, as well as the `CAN_INTR.GIRQ` bit.*

There are several interrupt events that can activate this `GIRQ` interrupt:

- Access denied interrupt (ADIM, ADIS, ADIF): At least one access to the mailbox RAM occurred during a data update by internal logic.
- Universal counter exceeded interrupt (UCEIM, UCEIS, UCEIF): There was an overflow of the universal counter (in Time Stamp mode or Event Counter mode) or the counter has reached the value 0x0000 (in Watchdog mode).
- Receive message lost interrupt (RMLIM, RMLIS, RMLIF): A message is received for a mailbox that currently contains unread data. At least one bit in the `CAN_RMLn` register is set. If the bit in `CAN_GIS` (and `CAN_GIF`) is cleared and there is at least one bit in `CAN_RMLn` still set, then the bit in `CAN_GIS` (and `CAN_GIF`) is not set again. The internal interrupt source signal is only active if a new bit in `CAN_RMLn` is set.
- Abort acknowledge interrupt (AAIM, AAIS, AAIF): At least one `AAn` bit in the `CAN_AAn` registers is set. If the bit in `CAN_GIS` (and `CAN_GIF`) is cleared and there is at least one bit in `CAN_AAn` still set, then the bit in `CAN_GIS` (and `CAN_GIF`) is not set again. The internal interrupt source signal is only active if a new bit in `CAN_AAn` is set. The `AAn` bits maintain state even after the corresponding mailbox `n` is disabled (`MCn = 0`).
- Access to unimplemented address interrupt (UIAIM, UIAIS, UIAIF): There was a CPU access to an address which is not implemented in the controller module.
- Wakeup interrupt (WUIM, WUIS, WUIF): The CAN module has left the sleep mode because of detected activity on the CAN bus line.
- Bus-Off interrupt (BOIM, BOIS, BOIF): The CAN module has entered the bus-off state. This interrupt source is active if the status of the CAN core changes from normal operation mode to the bus-off mode. If the bit in `CAN_GIS` (and `CAN_GIF`) is cleared and the bus-off mode is still active, then this bit is not set again. If the module leaves the bus-off mode, the bit in `CAN_GIS` (and `CAN_GIF`) remains set, if not explicitly cleared.
- Error-passive interrupt (EPIM, EPIS, EPIF): The CAN module has entered the error-passive state. This interrupt source is active if the status of the CAN module changes from the error-active mode to the error-passive mode. If the bit in `CAN_GIS` (and `CAN_GIF`) is cleared and the error-passive mode is still

active, then this bit is not set again. If the module leaves the error-passive mode, the bit in `CAN_GIS` (and `CAN_GIF`) remains set, if not explicitly cleared.

- Error warning receive interrupt (EWRIM, EWRIS, EWRIF): The CAN receive error counter (RXCNT) has reached the warning limit. If the bit in `CAN_GIS` (and `CAN_GIF`) is cleared and the error warning mode is still active, this bit is not set again. If the module leaves the error warning mode, the bit in `CAN_GIS` (and `CAN_GIF`) remains set, if not explicitly cleared.
- Error warning transmit interrupt (EWTIM, EWTIS, EWTIF): The CAN transmit error counter (TXCNT) has reached the warning limit. If the bit in `CAN_GIS` (and `CAN_GIF`) is cleared and the error warning mode is still active, this bit is not set again. If the module leaves the error warning mode, the bit in `CAN_GIS` (and `CAN_GIF`) remains set, if not explicitly cleared.

## CAN Event Counter

For diagnostic functions, it is possible to use the universal counter as an event counter. The counter can be programmed in the `CAN_UCCNF.UCCNF[3:0]` field to increment on one of these conditions:

- `UCCNF[3:0] = 0x6` – CAN error frame. Counter is incremented if there is an error frame on the CAN bus line.
- `UCCNF[3:0] = 0x7` – CAN overload frame. Counter is incremented if there is an overload frame on the CAN bus line.
- `UCCNF[3:0] = 0x8` – Lost arbitration. Counter is incremented every time arbitration on the CAN line is lost during transmission.
- `UCCNF[3:0] = 0x9` – Transmission aborted. Counter is incremented every time arbitration is lost or a transmit request is canceled (AAn is set).
- `UCCNF[3:0] = 0xA` – Transmission succeeded. Counter is incremented every time a message sends without detected errors (TAn is set).
- `UCCNF[3:0] = 0xB` – Receive message rejected. Counter is incremented every time a message is received without detected errors but not stored in a mailbox because there is no matching identifier found.
- `UCCNF[3:0] = 0xC` – Receive message lost. Counter is incremented every time a message is received without detected errors but not stored in a mailbox because the mailbox contains unread data (RMLn is set).
- `UCCNF[3:0] = 0xD` – Message received. Counter is incremented every time a message is received without detected errors, whether the received message is rejected or stored in a mailbox.
- `UCCNF[3:0] = 0xE` – Message stored. Counter is incremented every time a message is received without detected errors, has an identifier that matches an enabled receive mailbox, and is stored in the receive mailbox (RMPn is set).

- `UCCNF[3:0] = 0xF` – Valid message. Counter is incremented every time a valid transmit or receive message is detected on the CAN bus line.

## CAN Warnings and Errors

CAN warnings and errors are controlled using the Error Counter (`CAN_CEC`) register, the Error Status (`CAN_ESR`) register, and the Error Counter Warning Level (`CAN_EWR`) register.

### Programmable Warning Limits

It is possible to program the warning level for `EWTIS` and `EWRI` separately by writing to the `CAN_EWR.EWLREC` and `CAN_EWR.EWLTEC` fields. After power-on reset, the `CAN_EWR` register is set to the default warning level of 96 for both error counters. After soft reset, the contents of this register remain unchanged.

### Error Handling

Error management is an integral part of the CAN standard. Five different kinds of bus errors may occur during transmissions:

- Bit error – A bit error can be detected by the transmitting node only. Whenever a node is transmitting, it continuously monitors its receive pin (`CAN_RX`) and compares the received bit with the transmitted bit. During the arbitration phase, the node simply postpones the transmission if the received and transmitted bits do not match. However, after the arbitration phase (that is, once the `RTR` bit is sent successfully), a bit error is signaled any time the value on `CAN_RX` does not equal what is being transmitted on `CAN_TX`.
- Form error – A form error occurs any time a fixed-form bit position in the CAN frame contains one or more illegal bits-- that is, when a dominant bit is detected at a delimiter or end-of-frame bit position.
- Acknowledge error – An acknowledge error occurs whenever a message is sent and no receivers drive an acknowledge bit.
- CRC error – A CRC error occurs whenever a receiver calculates the CRC on the data it received and finds it different than the CRC that was transmitted on the bus itself.
- Stuff error – The CAN specification requires the transmitter to insert an extra stuff bit of opposite value after 5 bits have been transmitted with the same value. The receiver disregards the value of these stuff bits. However, it takes advantage of the signal edge to re-synchronize itself. A stuff error occurs on receiving nodes whenever the 6th consecutive bit value is the same as the previous five bits.

Once the CAN module detects any of the above errors, it updates the `CAN_ESR` and `CAN_CEC` registers. In addition to the standard errors, the `CAN_ESR` register features the `SA0` flag, which signals when the `CAN_RX` pin sticks at dominant level, indicating that shorted wires are likely.

## Error Frames

It is of central importance that all nodes on the CAN bus ignore data frames that one single node failed to receive. To accomplish this, every node sends an error frame as soon as it has detected an error. See the figure below.

Once a device has detected an error, it still completes the ongoing bit and initiates an Error Frame by sending six dominant and eight recessive bits to the bus. This is a violation to the bit stuffing rule and informs all nodes that the ongoing frame needs to be discarded.

All receivers that did not detect the transmission error in the first instance now detect a stuff bit error. The transmitter may detect a normal bit error sooner. It aborts the transmission of the ongoing frame and tries sending it again later.

Finally, all nodes on the bus have detected an error. Consequently, all of them send 6 dominant and 8 recessive bits to the bus as well. The resulting error frame consists of two different fields. The first field is given by the superposition of error flags contributed from the different stations, which is a sequence of 6 to 12 dominant bits. The second field is the error delimiter and consists of 8 recessive bits indicating the end of frame.

**Figure 21-9:** CAN Error Scenario Example

For CRC errors, the error frame is initiated at the end of the frame, rather than immediately after the failing bit.

After having received 8 recessive bits, every node knows that the error condition is resolved and starts transmission if messages are pending. The former transmitter that had to abort its operation must win the new arbitration again; otherwise its message is delayed as determined by priority.

Because the transmission of an error frame destroys the frame under transmission, a faulty node erroneously detecting an error can block the bus. Because of this, there are two node states which determine a

nodes right to signal an error—error-active and error-passive. Error-active nodes are those which have an error detection rate below a certain limit. These nodes drive an ‘Active Error Flag’ of 6 dominant bits.

Nodes with a higher error detection rate are suspected of having a local problem and, therefore, have a limited right to signal errors. These error-passive nodes drive a ‘Passive Error Flag’ consisting of 6 recessive bits. Thus, an error-passive transmitting node is still able to inform the other nodes about the abortion of a self-transmitted frame, but it is no longer able to destroy correctly received frames of other nodes.

## Error Levels

The CAN specification requires each node in the system to operate in one of three levels. See the table below. This prevents nodes with high error rates from blocking the entire network, as the errors might be caused by local hardware. The CAN module provides an error counter for transmit (TEC) and an error counter for receive (REC). The `CAN_CEC` register houses each of these 8-bit counters.

After initialization, both the TEC and the REC counters are 0. Each time a bus error occurs, one of the counters is incremented by either 1 or 8, depending on the error situation (documented in Version 2.0 of the CAN Specification). Successful transmit or receive operations decrement the respective counter by 1.

If either of the error counters exceeds 127, the CAN module goes into an error-passive state and the `CAN_STATUS.EP` bit is set. Once this happens, it is not allowed to send any more active error frames. However, it is still allowed to transmit messages and to signal passive error frames in case the transmission fails because of a bit error.

If one of the counters exceeds 255 (that is, when an 8-bit counter overflows), the CAN module is disconnected from the bus. It goes into Bus-Off mode and the `CAN_STAT.EBO` bit is set. Software intervention is required to recover from this state, unless the `CAN_CTL.ABO` bit is enabled, which allows entering of active mode after the Bus-Off recovery sequence.

**Table 21-5:** CAN Error Level Description

| Level         | Condition                                                              | Description                                                                                                                        |
|---------------|------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| Error active  | Transmit and receive error counters <128                               | This is the initial condition level. As long as errors stay below 128, the node will drive active error flags during error frames. |
| Error passive | Transmit or receive error counter value between 128 and 255, inclusive | Errors have accumulated to a level that requires the node to drive passive error flags during error frames.                        |
| Bus off       | Transmit or receive error counters greater than 255                    | CAN module goes into bus-off mode                                                                                                  |

In addition to these levels, the CAN module also provides a warning mechanism, which is an enhancement to the CAN specification. There are separate warnings for transmit and receive. By default, when one of the error counters exceeds 96, a warning is signaled and is represented in the `CAN_STAT` register by either

the CAN Receive Warning Flag (WR) bit when RXECNT is at limit; or CAN Transmit Warning Flag (WT) bit when TXECNT is at limit. The error warning level can be programmed using the error warning register (CAN\_EWR).

Additionally, interrupts can occur for all of these levels by unmasking them in the global CAN interrupt mask register (CAN\_GIM). These interrupts include the Bus-Off Interrupt (BOIM), the Error-Passive Interrupt (EPIM), the error warning receive interrupt (EWRIM), and the Error Warning Transmit Interrupt (EWTIM).

During the bus-off recovery sequence, the configuration mode request (CCR) bit in the CAN master control (CAN\_CTL) register is set by the internal logic, thus the CAN core module does not automatically come out of the bus-off mode. The CCR bit cannot be reset until the bus-off recovery sequence is finished.

*This behavior can be overridden by setting the auto bus-on (ABO) bit in the CAN\_CTL register. After exiting the bus-off or configuration modes, the CAN error counters are reset.*

## CAN Debug and Test Modes

The CAN module contains test mode features that aid in the debugging of the CAN software and system.

*When these features are used, the CAN module may not be compliant to the CAN specification. All test modes should be enabled or disabled only when the module is in Configuration mode (CCA = 1 in the CAN\_STAT register) or in Suspend mode (CSA = 1 in the CAN\_STAT register).*

The CAN\_DBG.CDE bit is used to gain access to all of the debug features. This bit must be set to enable the test mode, and it must be written first before subsequent writes to the CAN\_DBG register. When the CDE bit is cleared, all debug features are disabled.

When the CAN\_DBG.CDE bit is set, it enables writes to the other bits of the CAN\_DBG register. It also enables these features, which are not compliant with the CAN standard:

- Bit timing registers can be changed anytime, not only during configuration mode. This includes the CAN\_CLK and CAN\_TIMING registers.
- Write access is allowed to the normally read-only CAN\_CEC register.

The CAN\_DBG.MRB bit is used to enable the Readback mode. In this mode, a message transmitted on the CAN bus (or through an internal loopback mode) is received back directly to the internal receive buffer. After a correct transmission, the internal logic treats this as a normal receive message. This feature allows the user to test most of the CAN features without an external device.

The CAN\_DBG.MAA bit allows the CAN module to generate its own acknowledge during the ACK slot of the CAN frame. No external devices or connections are necessary to read back a transmit message. In this mode, the message that is sent is automatically stored in the internal receive buffer. In Auto Acknowledge mode, the module itself transmits the acknowledge. This acknowledge can be programmed to appear on the CAN\_TX pin if CAN\_DBG.DIL = 1 and CAN\_DBG.DTO = 0. If the acknowledge is only going to be used internally, then these test mode bits should be set to CAN\_DBG.DIL = 0 and CAN\_DBG.DTO = 1.

The CAN\_DBG.DIL bit is used to internally enable the transmit output to be routed back to the receive input.

The CAN\_DBG.DTO bit is used to disable the CAN\_TX output pin. When this bit is set, the CAN\_TX pin continuously drives recessive bits.

The CAN\_DBG.DRI bit is used to disable the CAN\_RX input. When set, the internal logic receives recessive bits or receives the internally generated transmit value in the case of the internal loop enabled (CAN\_DBG.DIL = 0). In either case, the value on the CAN\_RX input pin is ignored.

The CAN\_DBG.DEC bit is used to disable the Transmit and Receive Error Counters in the CAN\_CEC register. When this bit is set, the CAN\_CEC holds its current contents and is not allowed to increment or decrement the error counters. This mode does not conform to the CAN specification.

*Writes to the Error Counter registers should be performed in debug mode only. Write access during reception may lead to undefined values. The maximum value which can be written into the Error Counters is 255. Thus, the Error Counter value of 256, which forces the module into the bus off state, cannot be written into the Error Counter registers.*

## CAN Register Descriptions

Controller Area Network (CAN) contains the following registers.

**Table 21-7:** CAN Module Registers

| Name       | Description                                |
|------------|--------------------------------------------|
| CAN_MC1    | Mailbox Configuration 1 Register           |
| CAN_MD1    | Mailbox Direction 1 Register               |
| CAN_TRS1   | Transmission Request Set 1 Register        |
| CAN_TRR1   | Transmission Request Reset 1 Register      |
| CAN_TA1    | Transmission Acknowledge 1 Register        |
| CAN_AA1    | Abort Acknowledge 1 Register               |
| CAN_RMP1   | Receive Message Pending 1 Register         |
| CAN_RML1   | Receive Message Lost 1 Register            |
| CAN_MBTIF1 | Mailbox Transmit Interrupt Flag 1 Register |

**Table 21-7:** CAN Module Registers (Continued)

| Name        | Description                                              |
|-------------|----------------------------------------------------------|
| CAN_MBRI1F1 | Mailbox Receive Interrupt Flag 1 Register                |
| CAN_MBIM1   | Mailbox Interrupt Mask 1 Register                        |
| CAN_RFH1    | Remote Frame Handling 1 Register                         |
| CAN_OPSS1   | Overwrite Protection/Single Shot Transmission 1 Register |
| CAN_MC2     | Mailbox Configuration 2 Register                         |
| CAN_MD2     | Mailbox Direction 2 Register                             |
| CAN_TRS2    | Transmission Request Set 2 Register                      |
| CAN_TRR2    | Transmission Request Reset 2 Register                    |
| CAN_TA2     | Transmission Acknowledge 2 Register                      |
| CAN_AA2     | Abort Acknowledge 2 Register                             |
| CAN_RMP2    | Receive Message Pending 2 Register                       |
| CAN_RML2    | Receive Message Lost 2 Register                          |
| CAN_MBTIF2  | Mailbox Transmit Interrupt Flag 2 Register               |
| CAN_MBRI1F2 | Mailbox Receive Interrupt Flag 2 Register                |
| CAN_MBIM2   | Mailbox Interrupt Mask 2 Register                        |
| CAN_RFH2    | Remote Frame Handling 2 Register                         |
| CAN_OPSS2   | Overwrite Protection/Single Shot Transmission 2 Register |
| CAN_CLK     | Clock Register                                           |
| CAN_TIMING  | Timing Register                                          |
| CAN_DBG     | Debug Register                                           |
| CAN_STAT    | Status Register                                          |
| CAN_CEC     | Error Counter Register                                   |

**Table 21-7:** CAN Module Registers (Continued)

| Name               | Description                                   |
|--------------------|-----------------------------------------------|
| CAN_GIS            | Global CAN Interrupt Status Register          |
| CAN_GIM            | Global CAN Interrupt Mask Register            |
| CAN_GIF            | Global CAN Interrupt Flag Register            |
| CAN_CTL            | CAN Master Control Register                   |
| CAN_INT            | Interrupt Pending Register                    |
| CAN_MBTD           | Temporary Mailbox Disable Register            |
| CAN_EWR            | Error Counter Warning Level Register          |
| CAN_ESR            | Error Status Register                         |
| CAN_UCCNT          | Universal Counter Register                    |
| CAN_UCRC           | Universal Counter Reload/Capture Register     |

## Mailbox Configuration 1 Register

The CAN\_MC1 register enables mailboxes 0 through 15. Each bit in this register enables or disables the corresponding mailbox. For all bits, set the bit (=1) to enable the mailbox, and clear the bit (=0) to disable the mailbox.

Enabling and disabling mailboxes has an impact on transmit requests. Setting the CAN\_TRS1 bit associated with a disabled mailbox may result in erroneous behavior. Similarly, disabling a mailbox before the associated CAN\_TRS1 bit is reset by the internal logic can cause unpredictable results.

CAN\_MC1: Mailbox Configuration 1 Register - R/W

Reset = 0x0000

Figure 21-10: CAN\_MC1 Register Diagram

Table 21-8: CAN\_MC1 Register Fields

| Bit No. | Bit Name | Description/Enumeration   |
|---------|----------|---------------------------|
| 15:0    | MB       | Mailbox n Enable/Disable. |

## Mailbox Direction 1 Register

The CAN\_MD1 register selects the data transfer direction for mailboxes 0 through 15. Each bit in this register selects receive mode or transmit mode for the corresponding mailbox. For all bits, set the bit (=1) for transmit mode from the mailbox, and clear the bit (=0) for receive mode to the mailbox.

CAN\_MD1: Mailbox Direction 1 Register - R/W

Reset = 0x0000

Figure 21-11: CAN\_MD1 Register Diagram

**Table 21-9:** CAN\_MD1 Register Fields

| Bit No. | Bit Name | Description/Enumeration     |
|---------|----------|-----------------------------|
| 15:0    | MB       | Mailbox n Transmit/Receive. |

### Transmission Request Set 1 Register

The CAN\_TRS1 register requests transmit for mailboxes 0 through 15. Each bit in this register requests transmit for the corresponding mailbox when set (=1). After writing the data and the identifier into the mailbox area, the message is sent after mailbox n is enabled (with the corresponding bit in CAN\_MC1 = 1}, and (subsequently) the corresponding transmit request bit is set (in CAN\_TRS1). When a transmission completes, the corresponding bits in CAN\_TRS1 and in the transmit request reset register (CAN\_TRR1) are cleared.

**CAN\_TRS1: Transmission Request Set 1 Register - R/W**

Reset = 0x0000

**Figure 21-12:** CAN\_TRS1 Register Diagram

**Table 21-10:** CAN\_TRS1 Register Fields

| Bit No. | Bit Name | Description/Enumeration     |
|---------|----------|-----------------------------|
| 15:0    | MB       | Mailbox n Transmit Request. |

### Transmission Request Reset 1 Register

The CAN\_TRR1 register requests transmit abort for mailboxes 0 through 15. Each bit in this register requests transmit abort for the corresponding mailbox when set (=1). When a transmission completes, the corresponding bits in the transmit request set register (CAN\_TRS1) and in the CAN\_TRR1 are cleared.

CAN\_TRR1: Transmission Request Reset 1 Register - R/W

Reset = 0x0000

Figure 21-13: CAN\_TRR1 Register Diagram

Table 21-11: CAN\_TRR1 Register Fields

| Bit No. | Bit Name | Description/Enumeration   |
|---------|----------|---------------------------|
| 15:0    | MB       | Mailbox n Transmit Abort. |

Transmission Acknowledge 1 Register

The CAN\_TA1 register indicates transmission success for mailboxes 0 through 15. Each bit in this register indicates transmission success for the corresponding mailbox when set (=1).

CAN\_TA1: Transmission Acknowledge 1 Register - R/W

Reset = 0x0000

Figure 21-14: CAN\_TA1 Register Diagram

Table 21-12: CAN\_TA1 Register Fields

| Bit No. | Bit Name | Description/Enumeration         |
|---------|----------|---------------------------------|
| 15:0    | MB       | Mailbox n Transmit Acknowledge. |

Abort Acknowledge 1 Register

The CAN\_AA1 register indicates transmission abort (due to lost arbitration or a CAN error) for mailboxes 0 through 15. Each bit in this register indicates transmission abort for the corresponding mailbox when set (=1).

**CAN\_AA1: Abort Acknowledge 1 Register - R/W**

Reset = 0x0000

**Figure 21-15:** CAN\_AA1 Register Diagram

**Table 21-13:** CAN\_AA1 Register Fields

| Bit No. | Bit Name | Description/Enumeration      |
|---------|----------|------------------------------|
| 15:0    | MB       | Mailbox n Abort Acknowledge. |

**Receive Message Pending 1 Register**

The CAN\_RMP1 register indicates when a message is pending (unread data) for mailboxes 0 through 15. Each bit in this register indicates the message pending status for the corresponding mailbox when set (=1).

**CAN\_RMP1: Receive Message Pending 1 Register - R/W**

Reset = 0x0000

**Figure 21-16:** CAN\_RMP1 Register Diagram

**Table 21-14:** CAN\_RMP1 Register Fields

| Bit No. | Bit Name | Description/Enumeration    |
|---------|----------|----------------------------|
| 15:0    | MB       | Mailbox n Message Pending. |

**Receive Message Lost 1 Register**

The CAN\_RML1 register indicates when a message is lost---due to a message coming while there is pending data (corresponding CAN\_RMP1 bit set) and overwrite protection is disabled (CAN\_OPSS1 bit cleared)---for mailboxes 0 through 15. Each bit in this register indicates the message lost status for the corresponding mailbox when set (=1).

CAN\_RML1: Receive Message Lost 1 Register - R/W

Reset = 0x0000

Figure 21-17: CAN\_RML1 Register Diagram

Table 21-15: CAN\_RML1 Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 15:0    | MB       | Mailbox n Message Lost. |

Mailbox Transmit Interrupt Flag 1 Register

The CAN\_MBTIF1 register indicates when a transmit interrupt is pending---due to successful transmission (corresponding CAN\_TA1 bit set) and the interrupt is enabled (corresponding CAN\_MBIM1 bit set)---for mailboxes 0 through 15. Each bit in this register indicates the transmit interrupt pending status for the corresponding mailbox when set (=1). When any bit in CAN\_MBTIF1 is set, the CAN transmit interrupt request is raised (CAN\_INT.MBTIRQ bit set). To clear the interrupt request, all of the set bits in CAN\_MBTIF1 must be cleared by software (W1C). Also, software must clear the associated bits set in CAN\_TA1 or set the associated bits in CAN\_TRS1 bit to clear the interrupt source asserting the bits in CAN\_MBTIF1.

CAN\_MBTIF1: Mailbox Transmit Interrupt Flag 1 Register - R/W

Reset = 0x0000

Figure 21-18: CAN\_MBTIF1 Register Diagram

Table 21-16: CAN\_MBTIF1 Register Fields

| Bit No. | Bit Name | Description/Enumeration               |
|---------|----------|---------------------------------------|
| 15:0    | MB       | Mailbox n Transmit Interrupt Pending. |

## Mailbox Receive Interrupt Flag 1 Register

The CAN\_MBIF1 register indicates when a receive interrupt is pending---due to successful reception (corresponding CAN\_RMP1 bit set) and the interrupt is enabled (corresponding CAN\_MBIM1 bit set)---for mailboxes 0 through 15. Each bit in this register indicates the receive interrupt pending status for the corresponding mailbox when set (=1). When any bit in CAN\_MBIF1 is set, the CAN receive interrupt request is raised (CAN\_INT.MBIRQ bit set). To clear the interrupt request, all of the set bits in CAN\_RMP1 must be cleared by software, then the associated bits set in CAN\_MBIF1 must be cleared (W1C).

CAN\_MBIF1: Mailbox Receive Interrupt Flag 1 Register - R/W

Reset = 0x0000

Figure 21-19: CAN\_MBIF1 Register Diagram

| 15:0    | MB       | Mailbox n Receive Interrupt Pending. |

## Mailbox Interrupt Mask 1 Register

The CAN\_MBIM1 register enables transmit and receive interrupts for mailboxes 0 through 15. Each bit in this register requests enables the transmit or receive interrupt for the corresponding mailbox when set (=1).

CAN\_MBIM1: Mailbox Interrupt Mask 1 Register - R/W

Reset = 0x0000

Figure 21-20: CAN\_MBIM1 Register Diagram

Table 21-18: CAN\_MBIM1 Register Fields

|---------|----------|--------------------------------------------------|
| 15:0    | MB       | Mailbox n Transmit and Receive Interrupt Enable. |

Remote Frame Handling 1 Register

The CAN\_RFH1 register enables remote frame handling for mailboxes 0 through 15. Each bit in this register enables remote frame handling for the corresponding mailbox when set (=1). Note that enabling this bit affects transmit and receive operations for mailboxes. For more information about remote frame handling, see the CAN Operating Modes sections, describing transmit and receive operations.

CAN\_RFH1: Remote Frame Handling 1 Register - R/W

Reset = 0x0000

Figure 21-21: CAN\_RFH1 Register Diagram

Table 21-19: CAN\_RFH1 Register Fields

| Bit No. | Bit Name | Description/Enumeration                 |
|---------|----------|-----------------------------------------|
| 15:0    | MB       | Mailbox n Remote Frame Handling Enable. |

Overwrite Protection/Single Shot Transmission 1 Register

The CAN\_OPSS1 register enables overwrite protection for mailboxes 0 through 15. Each bit in this register enables overwrite protection for the corresponding mailbox when set (=1). Note that enabling this bit affects transmit and receive operations for mailboxes. For more information about remote overwrite protection, see the detailed feature description in the CAN Functional Description section. For more information about how this feature affects transmit and receive operations, see the CAN Operating Modes sections, describing transmit and receive operations.

**CAN\_OPSS1: Overwrite Protection/Single Shot Transmission 1 Register - R/W**

Reset = 0x0000

|---------|----------|----------------------------------------|
| 15:0    | MB       | Mailbox n Overwrite Protection Enable. |

**Mailbox Configuration 2 Register**

The CAN\_MC2 register enables mailboxes 16 through 31. Each bit in this register enables or disables the corresponding mailbox. For all bits, set the bit (=1) to enable the mailbox, and clear the bit (=0) to disable the mailbox.

Enabling and disabling mailboxes has an impact on transmit requests. Setting the CAN\_TRS2 bit associated with a disabled mailbox may result in erroneous behavior. Similarly, disabling a mailbox before the associated CAN\_TRS2 bit is reset by the internal logic can cause unpredictable results.

**CAN\_MC2: Mailbox Configuration 2 Register - R/W**

Reset = 0x0000

| Bit No. | Bit Name | Description/Enumeration     |
|---------|----------|-----------------------------|
| 15:0    | MB       | Mailbox n Transmit/Receive. |

## Transmission Request Set 2 Register

The CAN\_TRS2 register requests transmit for mailboxes 16 through 32. Each bit in this register requests transmit for the corresponding mailbox when set (=1). After writing the data and the identifier into the mailbox area, the message is sent after mailbox n is enabled (with the corresponding bit in CAN\_MC2 = 1}, and (subsequently) the corresponding transmit request bit is set (in CAN\_TRS2). When a transmission completes, the corresponding bits in CAN\_TRS2 and in the transmit request reset register (CAN\_TRR2) are cleared.

| Bit No. | Bit Name | Description/Enumeration     |
|---------|----------|-----------------------------|
| 15:0    | MB       | Mailbox n Transmit Request. |

## Transmission Request Reset 2 Register

The CAN\_TRR2 register requests transmit abort for mailboxes 16 through 32. Each bit in this register requests transmit abort for the corresponding mailbox when set (=1). When a transmission completes, the corresponding bits in the transmit request set register (CAN\_TRS2) and in the CAN\_TRR2 are cleared.

CAN\_TRR2: Transmission Request Reset 2 Register - R/W

Reset = 0x0000

## Mailbox Transmit Interrupt Flag 2 Register

The CAN\_MBTIF2 register indicates when a transmit interrupt is pending---due to successful transmission (corresponding CAN\_TA2 bit set) and the interrupt is enabled (corresponding CAN\_MBIM2 bit set)---for mailboxes 16 through 32. Each bit in this register indicates the transmit interrupt pending status for the corresponding mailbox when set (=1). When any bit in CAN\_MBTIF2 is set, the CAN transmit interrupt request is raised (CAN\_INT.MBTIRQ bit set). To clear the interrupt request, all of the set bits in CAN\_MBTIF2 must be cleared by software (W1C). Also, software must clear the associated bits set in CAN\_TA2 or set the associated bits in CAN\_TRS2 bit to clear the interrupt source asserting the bits in CAN\_MBTIF2.

**CAN\_MBTIF2: Mailbox Transmit Interrupt Flag 2 Register - R/W**

Reset = 0x0000

**Figure 21-31:** CAN\_MBTIF2 Register Diagram

Table 21-29: CAN\_MBTIF2 Register Fields

| Bit No. | Bit Name | Description/Enumeration                 |
|---------|----------|-----------------------------------------|
| 15:0    | MB       | Mailbox n Remote Frame Handling Enable. |

**Overwrite Protection/Single Shot Transmission 2 Register**

The CAN\_OPSS2 register enables overwrite protection for mailboxes 16 through 32. Each bit in this register enables overwrite protection for the corresponding mailbox when set (=1). Note that enabling this bit affects transmit and receive operations for mailboxes. For more information about remote overwrite

protection, see the detailed feature description in the CAN Functional Description section. For more information about how this feature affects transmit and receive operations, see the CAN Operating Modes sections, describing transmit and receive operations.

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9:8     | SJW      | <p>Synchronization Jump Width.</p> <p>The CAN_TIMING.SJW bits select the maximum number of time quanta, ranging from 1 to 4(SJW + 1). This selection allows for a re-synchronization attempt when the CAN detects a recessive-to-dominant edge outside the synchronization segment. The re-synchronization automatically moves the sampling point such that the CAN bit is still handled properly. Note that the CAN_TIMING.SJW value should not exceed CAN_TIMING.TSEG2 or CAN_TIMING.TSEG1.</p> |

**Table 21-35:** CAN\_TIMING Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7       | SAM      | <p>Sampling.</p> <p>The CAN_TIMING.SAM bit selects whether the CAN performs normal sampling (once at the sampling point described by the CAN_TIMING register) or performs over sampling. If CAN_TIMING.SAM is set, the CAN over samples the input signal at three times at the SCLK rate. The resulting value is generated by a majority decision of the three sample values. Note that the CAN_TIMING.SAM bit should always be cleared if the CAN_CLK.BRP value is less than 4.</p> |
| 6:4     | TSEG2    | <p>Time Segment 2.</p> <p>The CAN_TIMING.TSEG2 bits and CAN_TIMING.TSEG1 bits control how many time quanta of which the CAN bits consist, resulting in the CAN bit rate. For more information about bit timing and clock operation, see the CAN Operating Modes section. Note that the CAN_TIMING.TSEG1 value should always be greater than or equal to the CAN_TIMING.TSEG2 value.</p>                                                                                              |
| 3:0     | TSEG1    | <p>Time Segment 1.</p> <p>The CAN_TIMING.TSEG1 bits and CAN_TIMING.TSEG2 bits control how many time quanta of which the CAN bits consist, resulting in the CAN bit rate. For more information about bit timing and clock operation, see the CAN Operating Modes section. Note that the CAN_TIMING.TSEG1 value should always be greater than or equal to the CAN_TIMING.TSEG2 value.</p>                                                                                              |

## Debug Register

The CAN\_DBG register controls CAN debug modes, including CAN\_TX and CAN\_RX pin enable/disable.

**CAN\_DBG: Debug Register - R/W**

Reset = 0x0008

**Figure 21-38:** CAN\_DBG Register Diagram

**Table 21-36:** CAN\_DBG Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                      |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15      | CDE      | CAN Debug Mode Enable.<br>The CAN_DBG.CDE bit enables debug mode. This bit must be written first before subsequent writes to the CAN_DBG register. When the CAN_DBG.CDE bit is cleared, all CAN debug features are disabled. |
|         |          | 0      Disable Debug Mode                                                                                                                                                                                                    |
|         |          | 1      Enable Debug Mode                                                                                                                                                                                                     |
| 5       | MRB      | Mode Read Back.<br>The CAN_DBG.MRB bit enables read back mode. When enabled, a message transmitted on the CAN bus or through an internal loop back mode is received back directly to the internal receive buffer.            |
|         |          | 0      Disable Read Back Mode                                                                                                                                                                                                |
|         |          | 1      Enable Read Back Mode                                                                                                                                                                                                 |

**Table 21-36:** CAN\_DBG Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                           |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4       | MAA      | Mode Auto Acknowledge.<br>The CAN_DBG.MAA bit enables mode auto acknowledge, allowing the CAN to generate its own acknowledge during the ACK slot of the CAN frame. The CAN_DBG.MAA acknowledge appears on the CAN_TX pin if CAN_DBG.DIL =1 and CAN_DBG.DTO =0. If the acknowledge is only going to be used internally, these test mode bits should be set to CAN_DBG.DIL = 0 and CAN_DBG.DTO =1. |
|         |          | 0      Disable Auto Acknowledge Mode                                                                                                                                                                                                                                                                                                                                                              |
|         |          | 1      Enable Auto Acknowledge Mode                                                                                                                                                                                                                                                                                                                                                               |
| 3       | DIL      | Disable Internal Loop.<br>The CAN_DBG.DIL bit disables internal loop mode, which routes the transmit output to the receive input.                                                                                                                                                                                                                                                                 |
|         |          | 0      Enable Internal Loop                                                                                                                                                                                                                                                                                                                                                                       |
|         |          | 1      Disable Internal Loop                                                                                                                                                                                                                                                                                                                                                                      |
| 2       | DTO      | Disable Tx Output Pin.<br>The CAN_DBG.DTO bit disables the CAN_TX pin.                                                                                                                                                                                                                                                                                                                            |
|         |          | 0      Enable Tx Output Pin                                                                                                                                                                                                                                                                                                                                                                       |

| 1       | DRI      | Disable Receive Input Pin.<br>The CAN_DBG.DRI bit disables the CAN_RX pin.                                                                                                                                                                                                                                                                                                                        |
|         |          | 0      Enable Rx Input Pin                                                                                                                                                                                                                                                                                                                                                                        |
|         |          | 1      Disable Rx Input Pin, Drive Recessive Internally                                                                                                                                                                                                                                                                                                                                           |

**Table 21-36:** CAN\_DBG Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                        |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0       | DEC      | Disable Transmit and Receive Error Counters.<br>The CAN_DBG.DEC bit disables the transmit and receive error counters in the CAN_CEC register. When set, the CAN_CEC holds its current contents and is not allowed to increment or decrement the error counters. Note that this mode does not conform to the CAN specification. |
|         |          | 0 Enable CEC Tx and Rx Error Counters                                                                                                                                                                                                                                                                                          |
|         |          | 1 Disable CEC Tx and Rx Error Counters                                                                                                                                                                                                                                                                                         |

### Status Register

The CAN\_STAT register indicates status for CAN modes and error conditions.

**CAN\_STAT: Status Register - R/W**

Reset = 0x0000

## Error Counter Register

The CAN\_CEC register, CAN\_ESR register, and CAN\_EWR register control CAN warnings and errors. For detailed information about error and warning operations, see the Event Control section.

The CAN\_CEC register holds an error counter for transmit (CAN\_CEC.TXECNT) and an error counter for receive (CAN\_CEC.RXECNT). After initialization, both counters are 0. Each time a bus error occurs, one of the counters is incremented by either 1 or 8, depending on the error situation (documented in Version 2.0 of CAN Specification). Successful transmit and receive operations decrement the respective counter by 1.

Figure 21-40: CAN\_CEC Register Diagram

Table 21-38: CAN\_CEC Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                              |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:8    | TXECNT   | Transmit Error Counter.<br>The CAN_CEC.TXECNT bits hold the transmit error counter, which is incremented for errors (by either 1 or 8) and is decremented (by 1) for successful transmit operations. |
| 7:0     | RXECNT   | Receive Error Counter.<br>The CAN_CEC.RXECNT bits hold the receive error counter, which is incremented for errors (by either 1 or 8) and is decremented (by 1) for successful receive operations.    |

Global CAN Interrupt Status Register

The CAN\_GIS register, CAN\_GIF register, and CAN\_GIM register control CAN interrupts. For detailed information about interrupt operations, see the Event Control section.

The CAN\_GIS register holds the interrupt status. All bits in this register are W1C.

**CAN\_GIS: Global CAN Interrupt Status Register - R/W**

Reset = 0x0000

**Figure 21-41:** CAN\_GIS Register Diagram

**Table 21-39:** CAN\_GIS Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                             |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10      | ADIS     | Access Denied Interrupt Status.<br>The CAN_GIS.ADIS bit indicates when at least one access to the mailbox RAM occurred during a data update by internal logic.                                                                                      |
|         |          | 0 No Interrupt Pending                                                                                                                                                                                                                              |
|         |          | 1 Interrupt Pending                                                                                                                                                                                                                                 |
| 8       | UCEIS    | Universal Counter Exceeded Interrupt Status.<br>The CAN_GIS.UCEIS bit indicates when there has been an overflow of the universal counter (in time stamp mode or event counter mode) or the counter has reached the value 0x0000 (in watchdog mode). |
|         |          | 0 No Interrupt Pending                                                                                                                                                                                                                              |
|         |          | 1 Interrupt Pending                                                                                                                                                                                                                                 |

**Table 21-39:** CAN\_GIS Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7       | RMLIS    | Receive Message Lost Interrupt Status.<br>The CAN_GIS.RMLIS bit indicates when a message is received for a mailbox that currently contains unread data. At least one bit in the receive message lost register (CAN_RML1 or CAN_RML2) is set. If the bit in CAN_GIS (and CAN_GIF) is reset and there is at least one bit in CAN_RML1 or CAN_RML2 still set, the bit in CAN_GIF (and CAN_GIF) is not set again. The internal interrupt source signal is only active if a new bit in CAN_RML1 or CAN_RML2 is set.            |
|         |          | 0 No Interrupt Pending                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|         |          | 1 Interrupt Pending                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 6       | AAIS     | Abort Acknowledge Interrupt Status.<br>The CAN_GIS.AAIS bit indicates when At least one abort acknowledge bit is set in the CAN_AA1 or the CAN_AA2 registers. If the bit in CAN_GIS (and CAN_GIF) is reset and there is at least one bit in CAN_AA1 or CAN_AA2 still set, the bit in CAN_GIS (and CAN_GIF) is not set again. The internal interrupt source signal is only active if a new bit in CAN_AA1 or CAN_AA2 is set. The abort acknowledge bits maintain state even after the corresponding mailbox n is disabled. |

|         |          | 1Interrupt Pending                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 1       | EWRIS    | Error Warning Receive Interrupt Status.<br>The CAN_GIS.EWRIS bit indicates when the CAN_CEC.RXECNT has reached the warning limit. If the bit in CAN_GIS (and CAN_GIF) is reset and the error warning mode is still active, this bit is not set again. If the CAN leaves the error warning mode, the bit in CAN_GIS (and CAN_GIF) remains set.                                                                                                          |
|         |          | 0No Interrupt Pending                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|         |          | 1Interrupt Pending                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 21-39:** CAN\_GIS Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                        |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0       | EWTIS    | Error Warning Transmit Interrupt Status.<br>The CAN_GIS.EWTIS bit indicates when the CAN_CEC.TXECNT has reached the warning limit. If the bit in CAN_GIS (and CAN_GIF) is reset and the error warning mode is still active, this bit is not set again. If the CAN leaves the error warning mode, the bit in CAN_GIS (and CAN_GIF) remains set. |
|         |          | 0                      No Interrupt Pending                                                                                                                                                                                                                                                                                                    |
|         |          | 1                      Interrupt Pending                                                                                                                                                                                                                                                                                                       |

**Global CAN Interrupt Mask Register**

The CAN\_GIM register, CAN\_GIF register, and CAN\_GIF register control CAN interrupts. For detailed information about interrupt operations, see the Event Control section.

The CAN\_GIM register holds the interrupt mask. The interrupt mask bits only affect the content of the CAN\_GIF register. If the mask bit is not set (enabled/unmasked), the corresponding flag bit is not set when the event occurs.

**Figure 21-42:** CAN\_GIM Register Diagram

**Table 21-40:** CAN\_GIM Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                         |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------|
| 10      | ADIM     | Access Denied Interrupt Mask.<br>The CAN_GIM.ADIM bit enables (unmasks) the access denied interrupt.                            |
|         |          | 0      Disable Interrupt (Mask)                                                                                                 |
|         |          | 1      Enable Interrupt (Unmask)                                                                                                |
| 8       | UCEIM    | Universal Counter Exceeded Interrupt Mask.<br>The CAN_GIM.UCEIM bit enables (unmasks) the universal counter exceeded interrupt. |
|         |          | 0      Disable Interrupt (Mask)                                                                                                 |
|         |          | 1      Enable Interrupt (Unmask)                                                                                                |
| 7       | RMLIM    | Receive Message Lost Interrupt Mask.<br>The CAN_GIM.RMLIM bit enables (unmasks) the receive message lost interrupt.             |
|         |          | 0      Disable Interrupt (Mask)                                                                                                 |
|         |          | 1      Enable Interrupt (Unmask)                                                                                                |
| 6       | AAIM     | Abort Acknowledge Interrupt Mask.<br>The CAN_GIM.AAIM bit enables (unmasks) the abort acknowledge interrupt.                    |
|         |          | 0      Disable Interrupt (Mask)                                                                                                 |
|         |          | 1      Enable Interrupt (Unmask)                                                                                                |
| 5       | UIAIM    | Unimplemented Address Interrupt Mask.<br>The CAN_GIM.UIAIM bit enables (unmasks) the unimplemented address interrupt.           |
|         |          | 0      Disable Interrupt (Mask)                                                                                                 |
|         |          | 1      Enable Interrupt (Unmask)                                                                                                |

**Table 21-40:** CAN\_GIM Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                 |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------|
| 4       | WUIM     | Wake Up Interrupt Mask.<br>The CAN_GIM.WUIM bit enables (unmasks) the wake up interrupt.                                |
|         |          | 0 Disable Interrupt (Mask)                                                                                              |
|         |          | 1 Enable Interrupt (Unmask)                                                                                             |
| 3       | BOIM     | Bus Off Interrupt Mask.<br>The CAN_GIM.BOIM bit enables (unmasks) the bus off interrupt.                                |
|         |          | 0 Disable Interrupt (Mask)                                                                                              |
|         |          | 1 Enable Interrupt (Unmask)                                                                                             |
| 2       | EPIM     | Error Passive Interrupt Mask.<br>The CAN_GIM.EPIM bit enables (unmasks) the error passive mode interrupt.               |
|         |          | 0 Disable Interrupt (Mask)                                                                                              |
|         |          | 1 Enable Interrupt (Unmask)                                                                                             |
| 1       | EWRIM    | Error Warning Receive Interrupt Mask.<br>The CAN_GIM.EWRIM bit enables (unmasks) the error warning receive interrupt.   |
|         |          | 0 Disable Interrupt (Mask)                                                                                              |
|         |          | 1 Enable Interrupt (Unmask)                                                                                             |
| 0       | EWTIM    | Error Warning Transmit Interrupt Mask.<br>The CAN_GIM.EWTIM bit enables (unmasks) the error warning transmit interrupt. |
|         |          | 0 Disable Interrupt (Mask)                                                                                              |
|         |          | 1 Enable Interrupt (Unmask)                                                                                             |

## Global CAN Interrupt Flag Register

The CAN\_GIF register, CAN\_GIF register, and CAN\_GIM register control CAN interrupts. For detailed information about interrupt operations, see the Event Control section.

The CAN\_GIF register holds the interrupt flag. The CAN\_INT.GIRQ bit is only asserted if a bit in the CAN\_GIF is set. The CAN\_INT.GIRQ bit remains set as long as at least one bit in the CAN\_GIF register is set. All bits in this register are W1C.

**CAN\_GIF: Global CAN Interrupt Flag Register - R/NW**

Reset = 0x0000

**Figure 21-43: CAN\_GIF Register Diagram**

**Table 21-41: CAN\_GIF Register Fields**

| Bit No. | Bit Name | Description/Enumeration                                                                                                                       |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 10      | ADIF     | Access Denied Interrupt Flag.<br>The CAN_GIF.ADIF bit indicates the access denied interrupt flag is set (latched).                            |
|         |          | 0 No Interrupt Flag                                                                                                                           |
|         |          | 1 Interrupt Flag Set (Latched)                                                                                                                |
| 8       | UCEIF    | Universal Counter Exceeded Interrupt Flag.<br>The CAN_GIF.UCEIF bit indicates the universal counter exceeded interrupt flag is set (latched). |
|         |          | 0 No Interrupt Flag                                                                                                                           |
|         |          | 1 Interrupt Flag Set (Latched)                                                                                                                |

**Table 21-41:** CAN\_GIF Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                             |

| 4       | WUIF     | Wake Up Interrupt Flag.<br>The CAN_GIF.WUIF bit indicates the wake up interrupt flag is set (latched).                              |
|         |          | 0 No Interrupt Flag                                                                                                                 |
|         |          | 1 Interrupt Flag Set (Latched)                                                                                                      |
| 3       | BOIF     | Bus Off Interrupt Flag.<br>The CAN_GIF.BOIF bit indicates the bus off interrupt flag is set (latched).                              |
|         |          | 0 No Interrupt Flag                                                                                                                 |
|         |          | 1 Interrupt Flag Set (Latched)                                                                                                      |

**Table 21-41:** CAN\_GIF Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                            |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 2       | EPIF     | Error Passive Interrupt Flag.<br>The <code>CAN_GIF.EPIF</code> bit indicates the error passive mode interrupt flag is set (latched).               |
|         |          | 0 No Interrupt Flag                                                                                                                                |
|         |          | 1 Interrupt Flag Set (Latched)                                                                                                                     |
| 1       | EWRIF    | Error Warning Receive Interrupt Flag.<br>The <code>CAN_GIF.EWRIF</code> bit indicates the error warning receive interrupt flag is set (latched).   |
|         |          | 0 No Interrupt Flag                                                                                                                                |
|         |          | 1 Interrupt Flag Set (Latched)                                                                                                                     |
| 0       | EWTIF    | Error Warning Transmit Interrupt Flag.<br>The <code>CAN_GIF.EWTIF</code> bit indicates the error warning transmit interrupt flag is set (latched). |
|         |          | 0 No Interrupt Flag                                                                                                                                |
|         |          | 1 Interrupt Flag Set (Latched)                                                                                                                     |

## CAN Master Control Register

The `CAN_CTL` register controls CAN mode requests, including soft reset.

### CAN\_CTL: CAN Master Control Register - R/W

Reset = 0x0080

**Figure 21-44:** CAN\_CTL Register Diagram

**Table 21-42:** CAN\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                              |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7       | CCR      | CAN Configuration Mode Request.<br>The CAN_CTL.CCR bit requests that the CAN enter configuration mode. Note that the CAN should always be put in configuration mode before modifying the CAN_CLK or CAN_TIMING registers.            |
|         |          | 0 No Request (Exit Configuration Mode)                                                                                                                                                                                               |
|         |          | 1 Request Configuration Mode                                                                                                                                                                                                         |
| 6       | CSR      | CAN Suspend Mode Request.<br>The CAN_CTL.CSR bit requests that the CAN enter suspend mode. The CAN enters suspend mode after the current operation of the CAN bus is finished.                                                       |
|         |          | 0 No Request (Exit Suspend Mode)                                                                                                                                                                                                     |
|         |          | 1 Request Suspend Mode                                                                                                                                                                                                               |
| 5       | SMR      | Sleep Mode Request.<br>The CAN_CTL.SMR bit requests that the CAN enter sleep mode. The CAN enters sleep mode after the current operation of the CAN bus is finished.                                                                 |
|         |          | 0 No Request (Exit Sleep Mode)                                                                                                                                                                                                       |
|         |          | 1 Request Sleep Mode                                                                                                                                                                                                                 |
| 4       | WBA      | Wake Up on CAN Bus Activity.<br>The CAN_CTL.WBA bit enables wake on CAN bus activity. When enabled, a dominant bit on the CAN_RX pin ends sleep mode (in addition the default wake up condition of a write to the CAN_INT register). |
|         |          | 0 Disable Wake on Bus Activity                                                                                                                                                                                                       |
|         |          | 1 Enable Wake on Bus Activity                                                                                                                                                                                                        |

**Table 21-42:** CAN\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                  |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2       | ABO      | Auto Bus On.<br>The CAN_CTL.ABO bit selects whether (if enabled) the CAN enters active mode after the BusOff recovery sequence or (if disabled) the CAN enters configuration mode after the BusOff recovery sequence.    |
|         |          | 0      Disable Auto Bus On                                                                                                                                                                                               |
|         |          | 1      Enable Auto Bus On                                                                                                                                                                                                |
| 1       | DNM      | Device Net Mode.<br>The CAN_CTL.DNM bit enables mailbox filtering on a data field. The filtering is done on the standard ID of the message and data fields. For more information, see the CAN_AMnnH.FDF bit description. |
|         |          | 0      Disable Device Net Mode                                                                                                                                                                                           |
|         |          | 1      Enable Device Net Mode                                                                                                                                                                                            |
| 0       | SRS      | Software Reset.<br>The CAN_CTL.SRS bit resets the CAN, bringing all control registers to a defined state. Soft reset is entered immediately after software has set the CAN_CTL.SRS bit.                                  |
|         |          | 0      No Action                                                                                                                                                                                                         |
|         |          | 1      Reset CAN                                                                                                                                                                                                         |

## Interrupt Pending Register

The CAN\_INT register indicates the status of pending CAN interrupts and indicates the state of the CAN\_RX and CAN\_TX pins.

CAN\_INT: Interrupt Pending Register - R/W

Reset = 0x0000

Figure 21-45: CAN\_INT Register Diagram

Table 21-43: CAN\_INT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                   |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7       | CANRX    | Serial Input From Transceiver.<br>The CAN_INT.CANRX bit indicates the logic value that the CAN detects on the CAN_RX pin. Note that the reset/default value for CAN_INT.CANRX is dependent on pin values. |
|         |          | 0 Dominant Value (Low Active)                                                                                                                                                                             |
|         |          | 1 Recessive Value (High Active)                                                                                                                                                                           |
| 6       | CANTX    | Serial Input To Transceiver.<br>The CAN_INT.CANTX bit indicates the logic value that the CAN detects on the CAN_TX pin. Note that the reset/default value for CAN_INT.CANTX is dependent on pin values.   |
|         |          | 0 Dominant Value (Low Active)                                                                                                                                                                             |
|         |          | 1 Recessive Value (High Active)                                                                                                                                                                           |
| 3       | SMACK    | Sleep Mode Acknowledge.<br>The CAN_INT.SMACK bit indicates when the CAN has entered sleep mode.                                                                                                           |
|         |          | 0 Not in Sleep Mode                                                                                                                                                                                       |
|         |          | 1 Sleep Mode                                                                                                                                                                                              |

**Table 21-43:** CAN\_INT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                      |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2       | GIRQ     | Global CAN Interrupt Output.<br>The CAN_INT.GIRQ bit indicates when at least one bit is set in the CAN_GIF register, indicating at least one unmasked CAN is flagged (latched). The CAN_INT.GIRQ bit remains set as long as at least one bit is set in the CAN_GIF register. |
|         |          | 0 No CAN Global Interrupt Flag Set                                                                                                                                                                                                                                           |
|         |          | 1 CAN Global Interrupt Flag (1 or More) Set                                                                                                                                                                                                                                  |
| 1       | MBTIRQ   | Mailbox Transmit Interrupt Output.<br>The CAN_INT.MBTIRQ bit indicates when any bits are set in the CAN_MBTIF1 register or CAN_MBTIF2 register, indicating transmit.                                                                                                         |
|         |          | 0 No CAN Transmit Flags Set                                                                                                                                                                                                                                                  |
|         |          | 1 CAN Transmit Flags Set (1 or More)                                                                                                                                                                                                                                         |
| 0       | MBRIRQ   | Mailbox Receive Interrupt Output.<br>The CAN_INT.MBRIRQ bit indicates when any bits are set in the CAN_MBRIF1 register or CAN_MBRIF2 register, indicating receive.                                                                                                           |
|         |          | 0 No CAN Receive Flags Set                                                                                                                                                                                                                                                   |
|         |          | 1 CAN Receive Flags Set (1 or More)                                                                                                                                                                                                                                          |

## Temporary Mailbox Disable Register

The CAN\_MBTD register supports temporarily and selectively disabling CAN mailboxes. For more information about this feature, see the Operating Modes section.

### CAN\_MBTD: Temporary Mailbox Disable Register - R/W

Reset = 0x0000

**Figure 21-46:** CAN\_MBTD Register Diagram

**Table 21-44:** CAN\_MBTD Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                            |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7       | TDR      | Temporary Disable Request.<br>The CAN_MBTD.TDR bit hold the pointer to mailbox, which is disabled when the CAN_MBTD.TDR bit is set.                                                                                                                                                                |
|         |          | 0                      No Request                                                                                                                                                                                                                                                                  |
|         |          | 1                      Request Temporary Mailbox Disable                                                                                                                                                                                                                                           |
| 6       | TDA      | Temporary Disable Acknowledge.<br>The CAN_MBTD.TDA bit indicates when the mailbox (to which the CAN_MBTD.TDPTR bit point) is disabled. When this bit is set for a mailbox, only the data field of that mailbox may be updated. Accesses that mailbox's control bits and the identifier are denied. |
|         |          | 0                      No Acknowledge                                                                                                                                                                                                                                                              |
|         |          | 1                      Acknowledge Temporary Mailbox Disable                                                                                                                                                                                                                                       |
| 4:0     | TDPTR    | Temporary Disable Pointer.<br>The CAN_MBTD.TDPTR bits hold the pointer to mailbox, which is disabled when the CAN_MBTD.TDR bit is set.                                                                                                                                                             |

**Error Counter Warning Level Register**

The CAN\_EWR register, CAN\_CEC register, and CAN\_ESR register control CAN warnings and errors. For detailed information about error and warning operations, see the Operating Modes section.

**CAN\_EWR: Error Counter Warning Level Register - R/W**

Reset = 0x0000

**Figure 21-47:** CAN\_EWR Register Diagram

**Table 21-45:** CAN\_EWR Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                         |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:8    | EWLTEC   | Transmit Error Warning Limit.<br>The CAN_EWR.EWLTEC bits select the transmit error warning limit, which is used as a condition for the CAN_GIS.EWTIS interrupt. |
| 7:0     | EWLREC   | Receive Error Warning Limit.<br>The CAN_EWR.EWLREC bits select the receive error warning limit, which is used as a condition for the CAN_GIS.EWRIS interrupt.   |

### Error Status Register

The CAN\_ESR register, CAN\_CEC register, and CAN\_EWR register control CAN warnings and errors. All bits in the CAN\_ESR are W1C. Note that the CAN updates the CAN\_CEC register when error status is detected in the CAN\_ESR register. For detailed information about error and warning operations, see the Operating Modes section.

**CAN\_ESR: Error Status Register - R/W**

Reset = 0x0020

**Figure 21-48:** CAN\_ESR Register Diagram

**Table 21-46:** CAN\_ESR Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                   |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| 7       | FER      | Form Error.<br>The <code>CAN_ESR.FER</code> bit indicates when a form error occurs, indicating that a fixed-form bit position in the CAN frame contains one or more illegal bits. This occurs when a dominant bit is detected at a delimiter or end-of-frame bit position.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                   |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | No Status         |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Form Error        |
| 6       | BEF      | Bit Error Flag.<br>The <code>CAN_ESR.BEF</code> bit indicates (detected by the transmitting node only) the value on the <code>CAN_RX</code> pin does not equal what is being transmitted on the <code>CAN_TX</code> pin.<br>When a node is transmitting, it continuously monitors its receive pin ( <code>CAN_RX</code> ) and compares the received data with the transmitted data. The node postpones the transmission (during the arbitration phase) if the received and transmitted data do not match. After the arbitration phase ( <code>CAN_MBnn.ID1.RTR</code> bit sent successfully), a bit error is signaled when the value on the <code>CAN_RX</code> pin does not equal what is being transmitted on the <code>CAN_TX</code> pin. |                   |

| 3       | SER      | Stuff Bit Error.<br>The CAN_ESR.SER bit indicates when a stuff bit error (stuffed 6th consecutive bit value is the same as the previous five bits) occurs. The CAN specification requires that the transmitter insert an extra stuff bit of opposite value after 5 bits have been transmitted with the same value. The receiver disregards the value of these stuff bits. The receiver takes advantage of the signal edge to re-synchronize itself. A stuff bit error occurs on receiving nodes when the 6th consecutive bit value is the same as the previous five bits. |                         |

## Universal Counter Register

The `CAN_UCCNT` register holds the current universal count. This register is re-loaded from the `CAN_UCRC` register when the decrements to zero in auto-transmit mode.

CAN\_UCCNT: Universal Counter Register - R/W

Reset = 0x0000

| Bit No. | Bit Name | Description/Enumeration                                                          |
|---------|----------|----------------------------------------------------------------------------------|
| 15:0    | COUNT    | Count Value.<br>The CAN_UCCNT.COUNT bits hold the current universal count value. |

Universal Counter Reload/Capture Register

The CAN\_UCRC register holds the period value (universal count), which is used in auto-transmit mode as the period for sending the message in mailbox 11 (broadcast heartbeat) to all CAN nodes. Accordingly, messages sent this way usually have high priority.

The period value is written to the CAN\_UCRC register. When auto-transmit mode is enabled (CAN\_UCCNF.UCCNF = 0x3), the CAN loads the counter with the value in CAN\_UCRC. The counter decrements to 0 at the CAN bit clock rate, then is reloaded. Each time the counter decrements to 0, the CAN sets the CAN\_TRS1.MB bit for mailbox 11 and sends the corresponding message from mailbox 11.

Note that for auto-transmit mode, mailbox 11 must be configured as a transmit mailbox and must contain valid data (identifier, control bits, and data). This setup must occur before the counter first expires after this mode is enabled.

CAN\_UCRC: Universal Counter Reload/Capture Register - R/W

Reset = 0x0000

| Bit No. | Bit Name | Description/Enumeration                                                                                                                              |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0    | UCVAL    | Universal Counter Value.<br>The <code>CAN_UCRC.UCVAL</code> bits hold the value for the universal count period, which is used in auto-transmit mode. |

### Universal Counter Configuration Mode Register

The `CAN_UCCNF` register controls the operation of the universal counter, including counter enable and counter mode selection.

| 3:0     | DLC      | Data Length Code.<br>The CAN_MBnn_LENGTH.DLC bits hold the DLC value of the received remote frame. The received value overwrites any previous value. |

## Mailbox Timestamp Register

The CAN\_MBnn\_TIMESTAMP register holds an indication of the time of reception or transmission for each message, when the universal counter is in time stamp mode (CAN\_UCCNF.UCCNF =0x1). In this mode, the CAN writes the value of the counter (CAN\_UCCNT) to the CAN\_MBnn\_TIMESTAMP register when a received message is stored or a message is transmitted. For more information about timestamps, see the Time Stamps section.

## 22 Universal Serial Bus (USB)

The USB OTG controller provides a low-cost connectivity solution for consumer mobile devices such as cell phones, digital still cameras and MP3 players, allowing these devices to transfer data using a point-to-point USB connection without the need for a personal computer host.

The USB controller can operate in a traditional USB peripheral-only mode as well as the host mode presented in the On-The-Go (OTG) supplement <sup>1</sup> to the USB 2.0 Specification<sup>2</sup>In host mode, the USB module supports transfers at high-speed (480Mbps), full-speed (12Mbps), and low-speed (1.5 Mbp/sec) rates. Peripheral mode supports the high- and full-speed transfer rates.

The USB controller uses a peripheral bus slave interface to access its control and status registers as well as read and write to the endpoint packet buffers. Data is transferred to and from the USB controller through any of the 11 transmit and 11 receive endpoint FIFOs, EP1 - EP11, providing a total of 22 data endpoints.

### USB Features

The USB controller provides the following features:

- Low speed, full speed, high speed rates supported
- One bidirectional control endpoint
- Eleven transmit and eleven receive unidirectional endpoints
- 16 KB dynamically configured FIFO RAM
- Eight DMA master channels
- Two top-level maskable general purpose interrupts
- Low power wakeup on activity
- VBUS control interrupts for external analog VBUS control
- Session request protocol (SRP) and host negotiation protocol (HNP) capability
- Host transaction scheduling in hardware
- Soft connect/disconnect feature
- Full- and high-speed physical layer UTMI+ level 3 interface for on-chip PHY

---

1.On-The-Go Supplement to the USB 2.0 Specification, Rev 1.0a; June 24, 2003; USB-IF

2.Universal Serial Bus Specification 2.0

- Backwards compatible with existing USB 1.1 hosts
- Support for Battery Charging Specification Revision 1.1

The number of active endpoints at one time is only limited by device requirements or system bandwidth, because each endpoint operates independently from the next. Software determines the type of transfer for each endpoint individually and also the manner in which it is transferred between the USB controller and memory (DMA or interrupt-based). Endpoint zero is used solely for receive and transmit control transfers, which are used for device configuration and information gathering.

## USB Functional Description

The following sections describe the function of the USB OTG interface.

### USB Interface Overview

The USB controller operates in either of two USB operation modes (peripheral or host mode) at a given time.

In peripheral mode, the USB controller encodes, decodes, checks, and directs all USB packets sent and received, responding appropriately to host requests. Data is transferred from the processor core memory into the device's TX FIFOs to be transmitted onto USB as IN packets. In the other direction USB OUT packets are received into the RX FIFOs (having been sent from the host) and transferred to system memory for processing or storage. In peripheral mode, the USB controller acts as a slave device to another USB host; either a personal computer or another OTG host controller.

When operating in host mode, the USB controller uses simple hosting capabilities to master point-to-point connections with another USB peripheral, initiating transfers on the bus for the peripheral to respond. USB IN packets are received into the RX FIFOs to be moved into the processor core memory, and data written into TX FIFOs is transmitted onto the bus as USB OUT packets. In this mode, the USB controller encodes, decodes, and checks USB packets sent and received. The controller automatically schedules isochronous and interrupt transfers from the endpoint buffers such that one transaction is performed every  $n$  frames, where  $n$  represents the polling interval programmed for the endpoint.

Any of the endpoints can be programmed to be written to or read from using the DMA master channels to provide the most efficient means of transferring data between the controller and on-chip memory. USB endpoints 0 through 11 have DMA interrupt lines (USB\_DMAxINT) providing a total of eight DMA request lines. Two top-level maskable interrupts are provided, each of which can be sourced from any or all of transmit endpoint status, receive endpoint status or global USB status. Details of these can be found in [USB Interrupt Signals](#).

The USB controller uses the slave bus to access control and status registers and FIFOs from a slave perspective and to transfer data between the USB engine and on-chip memory as a master. The MMR peripheral data bus is 16-bits wide, the DMA data bus is 32-bits wide.

The USB controller's RAM interface supports a single block of synchronous single-port RAM used to buffer the USB packets. 16K bytes of SRAM are available.

The UTMI+ level 3 PHY interface provides a means of connecting a selection of high- or full-speed PHYs to the controller, from device-only PHYs through full OTG compliant PHYs. The details of the PHY interface can be found in [USB UTMI Interface](#).

**ATTENTION:** Check the processor data sheet for requirements regarding minimum system clock frequency needed for proper USB operation.

The USB controller is configured as either a USB OTG A device or B device depending on the type of plug inserted into its USB receptacle. This is determined by the state of the `USB_ID` (connector ID) pin.

The asynchronous wakeup circuit is used to detect when another 'B' device is asserting its D+ pull-up to initiate the SRP (session request protocol) when all other clocks are off. This circuit requires a slow clock (for example, 32kHz). This slow clock is derived from `SCLK` and enabled in the USB SRP clock divider register.

Use of the controller for OTG functionality requires the capability to drive `VBUS` (as a default A device powering the bus), to discharge `VBUS` (speeding up the time for `VBUS` to fall below the `SessionEnd` threshold as a 'B' device checking initial conditions), and to charge `VBUS` to 2.1V (when initiating SRP as a B device). These controls are driven from the UTMI interface, but the controller also provides a separate interrupt register, `USB_OTG_VBUS_IRQ`, which represents the drive `VBUS`, discharge `VBUS`, and charge `VBUS` signaling. See the `USB_OTG_VBUS_IRQ` register section for more information on these controls.

## Multi-point Support

The USB controller has the facility, when operating in Host mode, to act as the host to a range of USB peripheral devices – high-speed, full-speed or low-speed – where these devices are connected to the USB controller via a USB hub. The key feature of the controller's support for multiple devices is its facility to allow the functions of the target devices to be individually allocated to the different Rx and Tx endpoints implemented. Furthermore, this allocation can be made dynamically, allowing the devices from the targeted peripheral list to be used in different combinations. The combinations of peripheral devices that may be used together are limited by the numbers of Tx and Rx endpoints implemented in the controller. Further devices can only be added where the endpoints they require remain available.

## USB On-Chip Bus Interfaces

The USB controller uses two 32-bit wide independent bus interfaces, a master and a slave, to communicate with a processor-based subsystem. The slave interface allows the processor core to access the control and status registers (including DMA master registers) and the endpoint FIFOs. The master interface is used by the integrated DMA to drive data into or out of the endpoint FIFOs with minimal processor core interaction.

## USB FIFO Configuration

Each bidirectional endpoint (provided as two unidirectional endpoints) has its own endpoint number (0 for control, 1-11 for data transfer). Although two endpoints might use the same number, the endpoints may support different transfer types. Each of these bidirectional endpoints has a fixed region of the SRAM in the USB controller to which it has access, and this feature dictates to some extent the types of transfers that may be used for that particular endpoint. This restriction follows from the maximum size of USB packets, which varies with each transfer type. *FIFO Sizes and Transfer Types* lists the endpoint FIFO configuration, with an indication of the transfer types possible for that particular buffer size.

**Table 22-1:** FIFO Sizes and Transfer Types

| Bidirectional Endpoint<br>(RX and TX) | FIFO Size<br>(each direction)                              | USB Transfer Types               |
|---------------------------------------|------------------------------------------------------------|----------------------------------|
| 0                                     | 64 bytes                                                   | Size fixed for control transfers |
| 1-11                                  | Dynamically configured in powers of 2 from 8 to 8192 bytes | Bulk, Interrupt, Isochronous     |

Each endpoint FIFO can buffer one or two packets (in double-buffered mode). Double-buffering is recommended for most applications to improve efficiency by reducing the frequency with which each endpoint needs to be serviced. Double-buffering Bulk transactions means that data transfer over the USB is not slowed if packets can be loaded/unloaded from the FIFO in the time it takes to transfer a packet over the bus. Double-buffering isochronous transactions also allows more time to load/unload the FIFO, but in addition, it also allows the SOF interrupt to be used to service the endpoint rather than the endpoint interrupt. This has the following advantages:

- Easy detection of lost packets
- Regular interrupt timing (making it easier to source/sink the data)
- If more than one Isochronous endpoint is used, they can all be serviced with one interrupt.

## USB Power and Clocking

The USB controller uses the system clock `SCLK` to generate an internal clock used to clock the USB registers. The transceiver clock is a 60MHz clock sourced from the UTMI PHY and is used by the PHY interface logic and USB engine. A 32 KHz clock (refer to the `USB_SRP_CLKDIV` register) is used for D+ pulse detection for SRP signaling by an OTG B device only.

During SUSPEND and when no session is active, the clock to much of the USB controller is stopped to reduce power consumption. The clock becomes operational again when RESUME signaling is detected on the USB lines.

## USB UTMI Interface

The interface to the on-chip PHY uses the industry-standard UTMI+ (universal transceiver macro interface) level 3. This provides full high-speed device and OTG functionality and supports communication to a hub.

The PHY is a mixed-signal block and includes the following:

- Full-speed and high-speed drivers and receivers (single-ended and differential)
- Full-speed and high-speed CDR
- Full-speed/high-speed shift registers, NRZI encode/decode and bit-stuff encode/decode
- Data line pull-up and pull-down resistors
- VBUS and USB\_ID level detection
- Host disconnect detection

Although the UTMI specification indicates that VBUS charging, driving and discharging be done inside the PHY, for process-restricting and power reasons, these functions need to be implemented off-chip in a separate USB charge-pump chip.

## USB Register List

The universal serial bus (USB) controller is a multipoint high-speed dual role USB 2.0 compliant controller. The USB controller can operate in a traditional USB peripheral-only mode as well as the host mode presented in the on-the-go (OTG) supplement to the USB 2.0 Specification, Rev 1.0a; June 24, 2003; USB-IF. A set of registers govern USB controller operations. For more information on USB controller functionality, see the USB controller register descriptions.

**Table 22-2:** USB Module Registers

| Name        | Description                        |
|-------------|------------------------------------|
| USB_FADDR   | Function Address Register          |
| USB_POWER   | Power and Device Control Register  |
| USB_INTRTX  | Transmit Interrupt Register        |
| USB_INTRRX  | Receive Interrupt Register         |
| USB_INTRTXE | Transmit Interrupt Enable Register |
| USB_INTRRXE | Receive Interrupt Enable Register  |

**Table 22-2:** USB Module Registers (Continued)

| Name               | Description                            |
|--------------------|----------------------------------------|
| USB_IRQ            | Common Interrupts Register             |
| USB_IEN            | Common Interrupts Enable Register      |
| USB_FRAME          | Frame Number Register                  |
| USB_INDEX          | Index Register                         |
| USB_TESTMODE       | Testmode Register                      |
| USB_FIFOBn         | FIFO Byte (8-Bit) Register             |
| USB_FIFOHn         | FIFO Half-Word (16-Bit) Register       |
| USB_FIFOn          | FIFO Word (32-Bit) Register            |
| USB_DEV_CTL        | Device Control Register                |
| USB_TXFIFOSZ       | Transmit FIFO Size Register            |
| USB_RXFIFOSZ       | Receive FIFO Size Register             |
| USB_TXFIFOADDR     | Transmit FIFO Address Register         |

## USB Block Diagram

The USB block diagram shows the functional blocks within the USB. For more information about the blocks, see the [USB Functional Description](#).

**Figure 22-1:** USB OTG Controller Block Diagram

## USB Definitions

A list of common USB terms and their definitions as used in this specification and with respect to the USB controller follows:

### 'A' Device

The USB device with a mini-A plug inserted into its receptacle. The 'A' device always supplies power to VBUS.

### 'B' Device

The USB device with a standard-B or mini-B plug inserted into its receptacle. The B device starts a session as the peripheral.

### Bi-directional endpoint

An endpoint that can concurrently support receive and transfer packets.

### Control endpoint

An endpoint that is solely used for transfer of USB control packets for setup and configuration. In all USB devices, the control endpoint refers to the bi-directional endpoint 0.

### Dual role device

A USB device that can operate either as the USB host in an OTG session or as a traditional USB peripheral.

### Endpoint

A single physical communication channel for USB, implemented as a FIFO and control logic for that endpoint. Each endpoint has an associated USB transfer type, maximum packet size, bandwidth requirement, endpoint number, and (often) a fixed transfer direction.

### Frame

A regular, fixed 1ms time slot that can contain several transactions. The transfer type determines what transactions are permitted for a given endpoint.

### HNP

Host negotiation protocol. Part of the USB OTG Supplement that allows the host function to be transferred between two connected dual role devices.

### Packet

The lowest level of data exchange on USB. The size is determined by the transfer type and buffer size of the USB peripheral.

### PHY

The PHY is a transceiver circuit that implements the physical layer of USB. For full speed USB OTG this

includes line drivers and receivers, pull-up/pull-down resistors as well as device ID and VBUS level detection.

### **Session**

A period during which USB transfers take place within an OTG connection. This can be initiated by the 'A' device (by driving VBUS) or 'B' device (by initiating SRP). VBUS is powered during a session.

### **SRP**

Session request protocol. Part of the USB OTG Supplement that allows a 'B' device to turn on VBUS and initiate a USB session.

### **Transaction**

Collection of one or more packets in sequence

### **Transfer**

Collection of one or more transfers in sequence

### **Unidirectional endpoint**

Endpoint with its direction fixed in a single direction (for example, it can only receive packets from the USB) in both host and peripheral modes.

## **USB References**

The following references provide further information regarding the USB.

- *Universal Serial Bus Specification 2.0*

## **USB Operating Modes**

The USB OTG interface may operate in peripheral mode or host mode.

When the USB controller is operating in peripheral mode, the controller may be attached to a conventional host (such as a personal computer) or another OTG device operating in host mode. The second device can be high-speed or full-speed. When linked to another peripheral device, the USB controller can also act as the host, and if the other device is also a dual role controller, the two devices can switch roles as required.

The role taken by the USB controller depends on the way the devices are cabled together. Each USB cable has an 'A' and a 'B' device end. If the 'A' end of the cable is plugged into the device containing the USB controller, the USB controller takes the role of the host device and goes into host mode (in this case the

HOST\_MODE bit is set to 1). If the 'B' of the cable is plugged in, the USB controller goes instead into peripheral mode (and the HOST\_MODE bit remains at 0).

When both devices contain dual role controllers, signaling may be used to switch the roles of the two devices, without switching the cable connecting the two devices. The conditions under which the USB controller may switch between peripheral and host mode are detailed in [Host Negotiation/Configuration](#).

**NOTE:** The USB controller's Multi-Point capability is associated with a range of registers recording the allocation of device functions to individual USB controller's endpoints and device function characteristics such as endpoint number, operating speed and transaction type on an endpoint-by-endpoint basis. Although principally associated with the use of the USB controller as the host to a number of devices, these registers also need to be set when the core is used as the host for a single target device.

To enable the USB:

1. Configure the USB PLL multiplier settings in the USB PLL Control register. Check the processor data sheet for the input clock frequency requirements.
2. Enable the USB PHY by setting the enable bit (bit 7) in the PHY control register.
3. Poll the PLL\_STABLE bit in the USB PLL control register to ensure that the USB PLL has locked to the new frequency.

## USB Peripheral Mode

USB OTG interface operations for the peripheral mode differ from host mode in a number of ways. The following sections describe peripheral mode operations.

### Endpoint Setup

In peripheral mode, there are a few endpoint-specific configuration bits that are used when setting up an endpoint for transfer for all types of peripheral transfer. They determine how the processor core interacts with the endpoint FIFO.

One key parameter required before transfer can occur through an endpoint is the maximum USB packet size that the endpoint can support. This value is set by the software and depends on a variety of system constraints. These include the size of hardware FIFO available and system latencies as well as the USB transfer type and class being used. The USB\_TXMAXPn or USB\_RXMAXPn defines the maximum amount of data that can be transferred to the selected endpoint in a single frame, and the value must match the programmed maximum individual packet size (MaxPktSize) of the standard endpoint descriptor for the endpoint.

For TX endpoints, the maximum packet size is programmed using the USB\_RXMAXPn. For RX endpoints, the USB\_TXMAXPn register is used. The maximum packet size must not exceed the actual hardware endpoint FIFO size. The sizes of the transmit/receive FIFOs, as well as, single or double buffered mode for Endpoints 1 to 11 are determined by the settings in the corresponding FIFO\_SIZE register. Because the USB

controller uses a 32-bit interface, the value chosen for MaxPktSize should be an even number, as this selection simplifies transferring data between FIFOs and processor core.

Additional setup parameters are configured using the `USB_RXCSR` or `USB_TXCSR` register (depending on whether the endpoint in question is RX or TX). The `DMA_ENA` bit in this register is used to enable the assertion of the appropriate DMA request whenever the endpoint is able to receive or transmit another packet. The `AUTOCLEAR_R` and `AUTOSET_R/T` bits can be used to automatically set the FIFO ready triggers (`RXPKTRDY` and `TXPKTRDY`) whenever a packet is transferred to streamline DMA operation for transfers that span multiple packets. Note, however, that `AUTOCLEAR` and `AUTOSET` cannot be used with high-bandwidth endpoints. Refer to the Register Descriptions section for more details on the endpoint control and status registers.

## IN Transactions as a Peripheral

When the USB controller is operating in peripheral mode, data for IN transactions is handled through the TX FIFOs. The maximum size of data packet that may be placed in a TX endpoint's FIFO for transmission is programmable and (where applicable) is determined by the value written to the `USB_TXMAXPn` register for that endpoint (maximum payload multiplied by the number of transactions per micro-frame).

The maximum packet size set for any endpoint must not exceed the FIFO size. (See [USB FIFO Configuration](#).)

**ATTENTION:** The `USB_TXMAXPn` register should not be written-to while there is data in the FIFO, as unexpected results may occur.

For *single packet buffering*, as each packet to be sent is loaded into the TX FIFO, the `TXPKTRDY` bit in `USB_TXCSR` needs to be set. If the `AUTOSET_T` bit in `USB_TXCSR` is set, the `TXPKTRDY` bit is automatically set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, and where Auto Set may not be used (high-bandwidth Isochronous/Interrupt transactions) `TXPKTRDY` always has to be set manually (for example, set by the processor core).

When the `TXPKTRDY` bit is set, either manually or automatically, the `FIFO_NOT_EMPTY_T` bit in `USB_TXCSR` is also set and the packet is ready to be sent. When the packet is successfully sent, both `TXPKTRDY` and `FIFO_NOT_EMPTY_T` are cleared and the appropriate TX endpoint interrupt is generated (if enabled). The next packet can then be loaded into the FIFO.

For *double packet buffering*, as each packet to be sent is loaded into the TX FIFO, the `TXPKTRDY` bit in `USB_TXCSR` needs to be set. If the `AUTOSET_T` bit in `USB_TXCSR` is set, the `TXPKTRDY` bit automatically is set when a maximum-sized packet is loaded into the FIFO. For packet sizes less than the maximum, `TXPKTRDY` always has to be set manually (for example, set by the processor core). When the `TXPKTRDY` bit is set, either manually or automatically, the `FIFO_NOT_EMPTY_T` bit in `USB_TXCSR` also is set. The `TXPKTRDY` is then immediately cleared (and an interrupt generated, if enabled). A second packet can now be loaded into the TX FIFO and `TXPKTRDY` set again (either manually or automatically if the packet is the maximum size). Both packets are now ready to be sent.

When the first packet is successfully sent, `TXPKTRDY` is cleared and the appropriate TX endpoint interrupt is generated (if enabled) to signal that another packet can now be loaded into the TX FIFO. The state of the

`FIFO_NOT_EMPTY_T` bit at this point indicates how many packets may be loaded. If the `FIFO_NOT_EMPTY_T` bit is set then there is another packet in the FIFO and only one more packet can be loaded. If the `FIFO_NOT_EMPTY_T` bit is cleared then there are no packets in the FIFO and two more packets can be loaded.

## OUT Transactions as a Peripheral

When the USB controller is operating in peripheral mode, data for OUT transactions are handled through the USB controller's RX FIFOs.

The maximum amount of data received by an RX endpoint in any frame or micro-frame (in high-speed mode) is programmable and is determined by the value written to the `USB_RXMAXPn` register for that endpoint. This is the maximum payload multiplied by the number of transactions per micro-frame (where applicable). The maximum packet size must not exceed the FIFO size.

If the size of the RX endpoint FIFO is less than twice the maximum packet size for this endpoint (as set in the `USB_RXMAXPn` register), only one data packet can be buffered in the FIFO and single buffering is selected. When a packet is received and placed in the RX FIFO, the `RXPKTRDY` bit and the `FIFO_FULL` bit in `USB_RXCSR` are set and the appropriate RX endpoint interrupt is generated (if enabled) to signal that a packet can now be unloaded from the FIFO. After the packet is unloaded, the `RXPKTRDY` bit needs to be cleared in order to allow further packets to be received. If the `AUTOCLEAR_R` bit in `USB_RXCSR` is set and a maximum-sized packet is unloaded from the FIFO, the `RXPKTRDY` bit is cleared automatically. The `FIFO_FULL` bit is also cleared. For packet sizes less than the maximum, `RXPKTRDY` always has to be cleared manually (for example, set by the processor core).

If double packet buffering is enabled, then two data packets can be buffered. When the first packet to be received is loaded into the RX FIFO, the `RXPKTRDY` bit in `USB_RXCSR` is set and the appropriate RX endpoint interrupt is generated (if enabled) to signal that a packet can now be unloaded from the FIFO. Note that the `FIFO_FULL` bit in `USB_RXCSR` is not set at this point. This bit is only set if a second packet is received and loaded into the RX FIFO.

After the first packet is unloaded, `RXPKTRDY` needs to be cleared in order to allow further packets to be received. If the `AUTOCLEAR_R` bit in the `USB_RXCSR` register is set and a maximum-sized packet is unloaded from the FIFO, the `RXPKTRDY` bit is cleared automatically. For packet sizes less than the maximum, `RXPKTRDY` always has to be cleared manually (for example, set by the processor core).

If the `FIFO_FULL` bit was set to 1 when `RXPKTRDY` is cleared, the USB controller first clears the `FIFO_FULL` bit. The controller then sets `RXPKTRDY` again to indicate that there is another packet waiting in the FIFO to be unloaded.

## High-Bandwidth Isochronous/Interrupt Transactions

High-Bandwidth Isochronous/Interrupt transactions use much the same protocol as other Isochronous/Interrupt transactions. There are, however, some special features to conducting High-Bandwidth transactions.

- When setting the Maximum Packet size handled by the endpoint in the TxMaxP/RxMaxP register, the maximum number of transactions per microframe also needs to be set via bits D11 and D12 of that register.

This maximum number of transactions (2 or 3) also represents the maximum number of sections in which any single 'High-Bandwidth' packet can be transferred, which in turn sets the maximum size of packet to 2 or 3 times the maximum payload specified for the endpoint in the same register.

**NOTE:** The maximum payload that can be sent in any transaction is 1Kbyte.

- When sending packets, TxPktRdy needs to be set by the application software. Similarly, when unloading packets from the Rx endpoint FIFO, RxPktRdy needs to be cleared by the application software.

The AutoSet and AutoClear functions cannot be used to set and clear these bits in High-Bandwidth transactions.

- The transmission of packets as a number of sections introduces a further type of error – the transmission of Incomplete packets.

For Tx endpoints, the issue principally applies when the is in Peripheral mode and occurs when the fails to receive enough IN tokens from the host to send all the parts of the data packet. It can also apply to High-Bandwidth Interrupt transactions in Host mode where the core does not receive any response from the device to which the packet is being sent. In both cases, the will set the IncompTx bit in the TxCSR register (D7).

For Rx endpoints, the issue occurs when the PIDs of the received parts of the data packet show that one or more parts of the data packet has not been received. When this happens, the sets the IncompRx bit in the RxCSR register (D8). In the main, this bit will only be set when the core is operating in Peripheral mode but it can also be set in Host mode if (and only if) the device with which the is communicating fails to respond in accordance with the USB protocol.

## High Bandwidth Isochronous/Interrupt IN Endpoints

In high-speed mode, transmit endpoints set up for High-Bandwidth Isochronous/Interrupt transactions can transmit up to three USB packets in any micro-frame, with a payload of up to 1024 bytes in each packet, corresponding to a data transfer rate of up to 3072 bytes per micro-frame.

The following figure provides an overview of high-bandwidth IN endpoints in USB.

**Figure 22-2:** High Bandwidth IN Endpoints

The USB controller supports these transfers by permitting the loading of data packets with up to 3 times the normal packet size into the associated FIFO in a single transaction. From the point of view of the software in the processor core, the operation is then exactly as described above for single packet buffering or double packet buffering (as appropriate) except that `TXPKTRDY` always needs to be set manually (for example, set by the processor core) as the auto set feature does not operate with high-bandwidth isochronous transfers.

Any data packet loaded into the FIFO that is larger than the maximum payload is automatically split into USB packets of the maximum payload, or smaller, for transmission over the USB. The number of USB packets transmitted per micro-frame and the maximum payload in each packet is defined through the `USB_TXMAXPn` register. Bits 10-0 of the `USB_TXMAXPn` register determine the maximum payload in any USB packet while bits 12,11 determine the maximum number of such packets that can be sent in one micro-frame (2 or 3). Together, these set the maximum size of packet that can be loaded into the FIFO.

At least one USB packet always is sent. The number of further USB packets sent in the same micro-frame depends on the amount of data loaded into the FIFO. The `TXPKTRDY` bit is cleared and an interrupt is generated only when all the packets have been sent. Each USB packet is sent in response to an IN token. If, at the end of a micro-frame, the USB controller has not received enough IN tokens to send all the USB packets (for example, because one of the IN tokens received was corrupted), the remaining data is flushed

from the FIFO. The `TXPKTRDY` bit is cleared and the `INCOMPTX_T` bit in the `USB_TXCSR` register is set to indicate that not all of the data loaded into the FIFO was sent.

## High Bandwidth Isochronous/Interrupt OUT Endpoints

In high-speed mode, isochronous receive endpoints can receive up to three USB packets in any micro-frame, with a payload of up to 1024 bytes in each packet, corresponding to a data transfer rate of up to 3072 bytes per micro-frame. High-Bandwidth Interrupt transactions can similarly be received in Host mode, but note there is no support for high bandwidth Interrupt transactions in Peripheral mode.

The following figure shows an overview of high-bandwidth OUT endpoints.

The USB controller supports this rate by automatically combining all the USB packets received during a micro-frame into a single packet of up to 3 normal packets in size within the Rx FIFO. From the point of view of the software in the processor core, the operation is then exactly as described above for single packet buffering or double packet buffering (as appropriate), except the `RXPKTRDY` always needs to be cleared manually (for example, cleared by the processor core) as `AUTOCLEAR_R` does not operate with high-bandwidth isochronous transfers.

The maximum number of USB packets that may be received in any micro-frame and the maximum payload of these packets are defined through the `USB_RXMAXPn` register. Bits 10-0 of this register determine the maximum payload in any USB packet while bits 12,11 determine the maximum number of these packets that may be received in a micro-frame (2 or 3).

**Figure 22-3:** High Bandwidth OUT Endpoints

The number of USB packets sent in any micro-frame depends on the amount of data to be transferred, and is indicated through the PIDs used for the individual packets. If the indicated number of packets have not been received by the end of a micro-frame, the `INCOMPRX_R` bit in the `USB_RXCSR` register is set to indicate that the data in the FIFO is incomplete. Even so, an interrupt is still be generated to allow the data that has been received to be read from the FIFO.

## Peripheral Transfer Work Flows

The USB transfer types (control, bulk, isochronous and interrupt transfers) each have significantly different system requirements as well as individual USB transfer-specific features. This dictates that they are each dealt with slightly differently in software. For these reasons, there is no uniform way of doing transfers across all transfer types on the USB controller.

The following section provides some guideline peripheral mode transfer flows for each of the transfer types, in both IN (TX) and OUT (RX) directions. In the case of bulk endpoints, the optimal transfer flow differs depending on whether the final size of the transfer is known or unknown. Whether the transfer size is known or not depends on the USB driver class being used. Some define the complete transfer size, and

others operate on a packet-by-packet basis using a short packet (a packet of less than `USB_TXMAXPn` or less than `USB_RXMAXPn`) to denote the end of a transfer.

Each of the work flows use the following common method.

1. Configure the endpoint control and status registers and the `USB_TXMAXPn` or `USB_RXMAXPn` value.
2. Configure the appropriate data transfer mechanism (DMA or interrupt setup).
3. Data transfer phase

The work flows do not describe the USB controller's actions immediately preceding the endpoint setup (for example, the reception of an IN/OUT token from the host, token validity checking, or NAK generation, among others). Note also that there is currently no error-handling contained in the work flows (for example, checking `FIFO_FULL` bit before writing data).

The terms packets, frames and transfers are used in the proceeding sections with their strict USB definitions. (See the [USB Definitions](#) for these definitions.)

## Control Transactions as a Peripheral

Endpoint 0 is the main control endpoint of the USB controller. As such, the routines required to service Endpoint 0 are more complicated than those required to service other endpoints.

The software is required to handle all the Standard Device Requests that may be sent or received through Endpoint 0. These are described in *Universal Serial Bus Specification*, Revision 2.0, Chapter 9. The protocol for these device requests involves different numbers and types of transactions per transfer. To accommodate this, the processor needs to take a state machine approach to command decoding and handling.

The Standard Device Requests received by a USB peripheral can be divided into three categories: Zero Data Requests (in which all the information is included in the command), Write Requests (in which the command will be followed by additional data), and Read Requests (in which the device is required to send data back to the host).

This section looks at the sequence of actions that the software must perform to process these different types of device request.

## Write Requests

Write requests involve an additional packet (or packets) of data being sent from the host after the 8-byte command. An example of a 'Write' Standard Device Request is: `SET_DESCRIPTOR`.

The sequence of events will begin, as with all requests, when the software receives an Endpoint 0 interrupt. The `RxPktRdy` bit will also have been set. The 8-byte command should then be read from the Endpoint 0 FIFO and decoded.

As with a zero data request, the `USB_CSR0` register should then be written to set the `ServicedRxPktRdy` bit (indicating that the command is read from the FIFO) but in this case the `DataEnd` bit should not be set (indicating that more data is expected).

When a second Endpoint 0 interrupt is received, the `USB_CSR0` register is read to check the endpoint status. The `RxPktRdy` bit is set to indicate that a data packet is received. The `USB_COUNT0` register should then be read to determine the size of this data packet. The data packet can then be read from the Endpoint 0 FIFO.

If the length of the data associated with the request (indicated by the `wLength` field in the command) is greater than the maximum packet size for Endpoint 0, further data packets will be sent. In this case, `USB_CSR0` is written to set the `ServicedRxPktRdy` bit, but the `DataEnd` bit should not be set.

When all the expected data packets have been received, the `USB_CSR0` register is written to set the `ServicedRxPktRdy` bit and to set the `DataEnd` bit (indicating that no more data is expected).

When the host moves to the status stage of the request, another Endpoint 0 interrupt will be generated to indicate that the request has completed. No further action is required from the software-the interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or for some other reason cannot be executed, then when it has been decoded, the `USB_CSR0` register should be written to set the `ServicedRxPktRdy` bit and to set the `SendStall` bit. When the host sends more data, the USB controller will send a STALL to tell the host that the request was not executed. An Endpoint 0 interrupt will be generated and the `SentStall` bit will be set.

If the host sends more data after the `DataEnd` has been set, then the USB controller will send a STALL. An Endpoint 0 interrupt will be generated and the `SentStall` bit will be set.

## Read Requests

Read requests have a packet (or packets) of data sent from the function to the host after the 8-byte command. Examples of Standard Device Requests for Read are: `GET_CONFIGURATION`, `GET_INTERFACE`, `GET_DESCRIPTOR`, `GET_STATUS`, `SYNCH_FRAME`.

The sequence of events will begin, as with all requests, when the software receives an Endpoint 0 interrupt. The `RxPktRdy` bit in `USB_CSR0` will also have been set. The 8-byte command should then be read from the Endpoint 0 FIFO and decoded. The `USB_CSR0` register should then be written to set the `ServicedRxPktRdy` bit (indicating that the command has read from the FIFO).

The data to be sent to the host should then be written to the Endpoint 0 FIFO. If the data to be sent is greater than the maximum packet size for Endpoint 0, only the maximum packet size should be written to the FIFO. The `USB_CSR0` register should then be written to set the `TxPktRdy` bit (indicating that there is a packet in the FIFO to be sent). When the packet has been sent to the host, another Endpoint 0 interrupt will be generated and the next data packet can be written to the FIFO.

When the last data packet has been written to the FIFO, the `USB_CSR0` register should be written to set the `TxPktRdy` bit and to set the `DataEnd` bit (indicating that there is no more data after this packet).

When the host moves to the status stage of the request, another Endpoint 0 interrupt will be generated to indicate that the request has completed. No further action is required from the software-the interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or for some other reason cannot be executed, then when it has been decoded, the `USB_CSR0` register should be written to set the `ServicedRxPktRdy` bit and to set the

SendStall bit. When the host requests data, the USB controller will send a STALL to tell the host that the request was not executed. An Endpoint 0 interrupt will be generated and the SentStall bit will be set.

If the host requests more data after DataEnd has been set, then the USB controller will send a STALL. An Endpoint 0 interrupt will be generated and the SentStall bit will be set.

## Zero Data Requests

Zero data requests have all their information included in the 8-byte command and require no additional data to be transferred.

Examples of zero data Standard Device Requests are: SET\_FEATURE, CLEAR\_FEATURE, SET\_ADDRESS, SET\_CONFIGURATION, SET\_INTERFACE.

The sequence of events will begin, as with all requests, when the software receives an Endpoint 0 interrupt. The RxPktRdy bit will also have been set. The 8-byte command should then be read from the Endpoint 0 FIFO, decoded and the appropriate action taken. For example if the command is SET\_ADDRESS, the 7-bit address value contained in the command is written to the USB\_FADDR register.

The USB\_CSR0 register should then be written to set the ServicedRxPktRdy bit (indicating that the command is read from the FIFO) and to set the DataEnd bit (indicating that no further data is expected for this request).

When the host moves to the status stage of the request, a second Endpoint 0 interrupt will be generated to indicate that the request has completed. No further action is required from the software-the second interrupt is just a confirmation that the request completed successfully.

If the command is an unrecognized command, or for some other reason cannot be executed, then when it is decoded, the USB\_CSR0 register is written to set the ServicedRxPktRdy bit and to set the SendStall bit. When the host moves to the status stage of the request, the USB controller will send a STALL to tell the host that the request was not executed. A second Endpoint 0 interrupt will be generated and the SentStall bit will be set.

If the host sends more data after the DataEnd bit is set, then the USB controller will send a STALL. An Endpoint 0 interrupt will be generated and the SentStall bit will be set.

## ENDPOINT 0 States

When the USB is operating as a peripheral, the Endpoint 0 control needs three modes (IDLE, TX and RX) corresponding to the different phases of the control transfer and the states Endpoint 0 enters for the different phases of the transfer. (See [Endpoint 0 Service Routine as Peripheral](#).)

The default mode on power-up or reset should be IDLE. The RxPktRdy bit becoming set when Endpoint 0 is in IDLE state indicates a new device request. Once the device request is unloaded from the FIFO, the USB decodes the descriptor to find whether there is a data phase and, if so, the direction of the data phase of the control transfer (in order to set the FIFO direction).

Depending on the direction of the data phase, Endpoint 0 goes into either TX state or RX state. If there is no data phase, Endpoint 0 remains in IDLE state to accept the next device request.

The processor needs to take different actions at the different phases of the possible transfers (for example, "Loading the FIFO", "Setting TxPktRdy") are indicated in the [Endpoint 0 Control States](#) figure. Note that the USB changes the FIFO direction depending on the direction of the data phase, independently of the processor.

**Figure 22-4:** Endpoint 0 Control States

## Endpoint 0 Service Routine as Peripheral

An Endpoint 0 interrupt is generated:

- When the USB controller sets the RxPktRdy bit after a valid token has been received and data has been written to the FIFO.
- When the USB controller clears the TxPktRdy bit after the data packet in the FIFO has been successfully transmitted to the host.

- When the USB controller sets the `SentStall` bit after a control transaction is ended due to a protocol violation.
- When the USB controller sets the `SetupEnd` bit because a control transfer has ended before `DataEnd` is set.

The bits mentioned above, are in the `USB_CSR0` register.

Whenever the Endpoint 0 service routine is entered, the firmware must first check whether the current control transfer has been ended due to either a STALL condition or a premature end-of-control transfer. If the control transfer ends due to a STALL condition, the `SentStall` bit would be set. If the control transfer ends due to a premature end-of-control transfer, the `SetupEnd` bit would be set. In either case, the firmware should abort processing the current control transfer and set the state to IDLE.

Once the firmware has determined that the interrupt was not generated by an illegal bus state, the next action depends on the Endpoint state.

If Endpoint 0 is in IDLE state, the only valid reason an interrupt can be generated is as a result of the core receiving data from the USB bus. The service routine must check for this by testing the `RxPktRdy` bit. If this bit is set, then the core has received a SETUP packet. This must be unloaded from the FIFO and decoded to determine the action the core must take. Depending on the command contained within the SETUP packet, Endpoint 0 will enter one of three states:

- If the command is a single packet transaction (`SET_ADDRESS`, `SET_INTERFACE` etc.) without a data phase, the endpoint will remain in IDLE state.
- If the command has an OUT data phase (`SET_DESCRIPTOR` etc.), the endpoint will enter RX state.
- If the command has an IN data phase (`GET_DESCRIPTOR` etc.), the endpoint will enter TX state.

If the endpoint is in TX state, the interrupt indicates that the core has received an IN token and data from the FIFO has been sent. The firmware must respond to this either by placing more data in the FIFO if the host is still expecting more data<sup>1</sup> or by setting the `DataEnd` bit to indicate that the data phase is complete. Once the data phase of the transaction has been completed, Endpoint 0 should be returned to IDLE state to await the next control transaction.

If the endpoint is in RX state, the interrupt indicates that a data packet has been received. The firmware must respond by unloading the received data from the FIFO. The firmware must then determine whether it has received all of the expected data. If it has, the firmware should set the `DataEnd` bit and return Endpoint 0 to IDLE state. If more data is expected, the firmware should set the `ServicedRxPktRdy` bit to indicate that it has read the data in the FIFO and leave the endpoint in RX state.

---

1. Command transactions all include a field that indicates the amount of data the host expects to receive or is going to send.

**Figure 22-5:** Endpoint 0 Service Routine

## Idle Mode

The Endpoint 0 control must select the IDLE mode at power-on or reset. The Endpoint 0 control should return to this mode when the RX and TX modes are terminated.

This is also the mode in which the SETUP phase of control transfer is handled. (See the [Endpoint 0 Idle Mode \(Setup Phase\)](#) figure.)

**Figure 22-6:** Endpoint 0 Idle Mode (Setup Phase)

## TX Mode

When the endpoint is in TX state, all arriving IN tokens need to be treated as part of a data phase until the required amount of data has been sent to the host. If either a SETUP or an OUT token is received while the endpoint is in the TX state, a `SetupEnd` condition would occur since the core expects only IN tokens.

Three events can cause the TX mode to terminate before the expected amount of data has been sent:

- The host sends an invalid token causing a `SetupEnd` bit set.
- The firmware sends a packet containing less than the maximum packet size for Endpoint 0.
- The firmware sends an empty data packet.

Until the transaction is terminated, when the firmware receives an interrupt which indicates that a packet has been sent from the FIFO, it simply loads the FIFO. An interrupt is generated when `TxPktRdy` is cleared.

When the firmware forces the termination of a transfer (by sending a short or empty data packet), it should set the `DataEnd` bit to indicate to the core that the data phase is complete and that the core should receive an acknowledge packet next.

**Figure 22-7:** Endpoint 0 TX Mode

## RX Mode

In RX mode, all arriving data should be treated as part of a data phase until the expected amount of data has been received. If either a SETUP or an IN token is received while the endpoint is in RX state, a SetupEnd condition would occur since the core expects only OUT tokens.

Three events can cause the RX mode to terminate before the expected amount of data has been received:

- The host sends an invalid token causing a SetupEnd bit set.
- The host sends a packet which contains less than the maximum packet size for Endpoint 0.
- The host sends an empty data packet.

Until the transaction is terminated, when the firmware receives an interrupt which indicates that new data has arrived (RxPktRdy bit set), it simply needs to unload the FIFO and clear RxPktRdy by setting the ServicedRxPktRdy bit.

When the firmware detects the termination of a transfer (by receiving either the expected amount of data or an empty data packet), it should set the DataEnd bit to indicate to the core that the data phase is complete and that the core should receive an acknowledge packet next.

**Figure 22-8:** Endpoint 0 RX Mode

### Peripheral Mode, Bulk IN, Transfer Size Known

*PREREQUISITE:*

For this process, the maximum individual packet size (*MaxPktSize*) in bytes and the complete transfer size (*TxferSize*) in bytes, must be known.

1. Load *MaxPktSize* into USB\_TXMAXPn.
2. Set DMA\_ENA = 1, AUTOSET\_T = 1, ISO\_T = 0, FRCDATATOG = 0 in USB\_TXCSR.
3. Load *TxferSize* into USB\_DMA\_CNTn.
4. Configure the DMA controller to write the data into the corresponding TX FIFO address.
5. On each USB\_DMAxINT transition, the DMA controller writes a new packet into the FIFO. TXPKTRDY is automatically set when each new packet is written.
6. Step 5 is repeated for each full packet of the transfer.
7. Even if the final packet is a short packet, the packet automatically is detected by the USB controller because TXPKTRDY is set.

## Peripheral Mode, Bulk IN, Transfer Size Unknown

### PREREQUISITE:

For this process, the maximum individual packet size (*MaxPktSize*) in bytes is assumed to be an even number of bytes.

1. Load *MaxPktSize* into USB\_TXMAXPn.
2. Set DMA\_ENA = 1, AUTOSET\_T = 1, ISO\_T = 0, FRCDATATOG = 0 in USB\_TXCSR.
3. Configure the DMA controller to write *MaxPktSize*/2 half words into the corresponding TX FIFO address on each USB\_DMAxINT.
4. Set up an ISR, sensitive to the DMA work-block-complete interrupt, that writes a remaining short packet into the TX FIFO using processor core DMA. Then set TXPKTRDY or simply send a zero-length packet by toggling TXPKTRDY.
5. On each USB\_DMAxINT transition, the DMA controller writes a new packet into the FIFO. TXPKTRDY automatically is set when each new packet is written.
6. Step 5 is repeated for each full packet of the transfer.
7. The final short/zero-length packet is managed by the ISR from step 4.

## Peripheral Mode, ISO IN, Small MaxPktSize

### PREREQUISITE:

For this process, the maximum individual packet size (*MaxPktSize*) in bytes is less than 128 bytes and is an even number of bytes. Double buffering is assumed to be enabled, and the auto set feature unused (because packets are often less than *MaxPktSize*).

1. Load *MaxPktSize* into USB\_TXMAXPn.
2. Set ISO\_T = 1 in USB\_TXCSR.
3. Preload the first two packets into the endpoint TX FIFO and set TXPKTRDY.
4. Set up an ISR, sensitive to the SOF\_B interrupt, which writes a new packet into the TX FIFO and sets TXPKTRDY.
5. Set SOF\_B = 1 in USB\_INTRUSBE to generate an interrupt on each start-of-frame.
6. Step 5 is repeated for each ISO packet.

## Peripheral Mode, ISO IN, Large MaxPktSize

### PREREQUISITE:

For this process, the maximum individual packet size (*MaxPktSize*) in bytes is greater than 128 bytes and is an even number of bytes. Double buffering is assumed to be enabled, and the auto set feature unused (because packets are often less than *MaxPktSize*).

1. Load *MaxPktSize* into USB\_TXMAXPn.
2. Set ISO\_T = 1 in USB\_TXCSR.
3. Set ISO\_UPDATE = 1 in USB\_POWER to prevent initial packet loaded into the FIFO from being transmitted on USB until the next 1ms frame.
4. Load the total number of bytes for the first two packets into USB\_DMA\_CNTn.
5. Configure the DMA controller to pre-load the two packets into the corresponding TX FIFO address. Set TXPKTRDY.
6. Set up an ISR, sensitive to the SOF\_B interrupt, which writes a new packet into the TX FIFO by configuring the DMA controller to load the packet.
7. Set SOF\_B = 1 in USB\_INTRUSBE to generate an interrupt on each start-of-frame.
8. Step 7 is repeated for each ISO packet.

## Peripheral Mode, Bulk OUT, Transfer Size Known

### PREREQUISITE:

For this process, the maximum individual packet size (*MaxPktSize*) in bytes and the complete transfer size (*TxferSize*) in bytes must be known.

1. Load *MaxPktSize* into USB\_RXMAXPn.
2. Set DMA\_ENA = 1, AUTOCLEAR\_R = 1, ISO\_R = 0, FRCDATATOG = 0, DMAREQMODE\_R = 0 in USB\_RXCSR.
3. Configure the DMA controller to read the full *TxferSize*/2 half words from the corresponding RX FIFO address.
4. On each USB\_DMAxINT transition, the DMA controller reads another packet from the FIFO. RXPKTRDY is automatically cleared by the USB controller when each new packet is read.
5. Step 5 is repeated for each full packet of the transfer.
6. If *TxferSize* is not an exact multiple of *MaxPktSize*, the final USB\_DMAxINT transition causes the DMA controller to read out only the short packet that remains.

## Peripheral Mode, Bulk OUT, Transfer Size Unknown

### PREREQUISITE:

For this process, the maximum individual packet size (*MaxPktSize*) in bytes must be known.

1. Load *MaxPktSize* into USB\_RXMAXPn.
2. Set DMA\_ENA = 1, AUTOCLEAR\_R = 1, ISO\_R = 0, FRCDATATOG = 0, DMAREQMODE\_R = 1 in USB\_RXCSR.
3. Set the appropriate EPx\_RX\_E bit in USB\_INTRRXE.
4. Configure the DMA controller to read *MaxPktSize*/2 half words from the corresponding RX FIFO address on each USB\_DMAxINT transition.
5. Set up an ISR, sensitive to the RX interrupt, which reads USB\_RXCOUNT and then transfers USB\_RXCOUNT bytes (in half words) from the RX FIFO to the processor core. Depending on the number of bytes in the FIFO, this can be performed by configuring the DMA to read the data, or by reading it with the processor core.
6. On each USB\_DMAxINT transition, the DMA controller reads a packet from the FIFO. RXPkTRDY is automatically cleared by the USB controller when each new packet is read.
7. Step 5 is repeated for each full packet of the transfer.
8. If a packet is received that is less than *MaxPktSize*, the RX interrupt goes high, and the ISR from step 5 reads out the remaining short packet.

## Peripheral Mode, ISO OUT, Small MaxPktSize

### PREREQUISITE:

For this process, the maximum individual packet size (*MaxPktSize*) in bytes is less than 128 bytes, and double buffering is assumed to be enabled.

1. Load *MaxPktSize* into USB\_RXMAXPn.
2. Set ISO\_R = 1 in USB\_RXCSR.
3. Set up an ISR, sensitive to the SOF\_B interrupt, that reads the FIFO\_FULL bit, reads the USB\_RXCOUNT status register, and finally removes one or two packets (equal to the USB\_RXCOUNT number of bytes) from the FIFO then clears RXPkTRDY.
4. Set SOF\_B = 1 in USB\_INTRUSBE to generate an interrupt on each start-of-frame.
5. Step 4 is repeated for each ISO packet.

## Peripheral Mode, ISO OUT, Large MaxPktSize

### PREREQUISITE:

For this process, the maximum individual packet size (*MaxPktSize*) in bytes is greater than 128 bytes, and double buffering is assumed to be enabled.

1. Load *MaxPktSize* into the USB\_RXMAXPn register.
2. Set the ISO\_R = 1 in the USB\_RXCSR register.
3. Set up an ISR, (sensitive to the SOF\_B interrupt), that reads the FIFO\_FULL bit, reads the USB\_RXCOUNT status register, and finally configures the DMA controller to remove one or two packets (equal to the USB\_RXCOUNT number of bytes) from the FIFO.
4. Set up an ISR, sensitive to the DMA work-block-complete interrupt to clear RXPKTRDY.
5. Set SOF\_B = 1 in the USB\_INTRUSBE register to generate an interrupt on each start-of-frame.
6. Step 5 is repeated for each ISO packet.

## Peripheral Mode Suspend

When no activity has occurred on the USB for 3 ms, the USB controller enters suspend mode. If the suspend interrupt (SUSPEND\_B) is enabled, an interrupt is generated at this time.

When resume signaling is detected, the USB controller exits suspend mode. If the RESUME\_B interrupt is enabled, an interrupt is generated. The processor core can also force the USB controller to exit suspend mode by setting the RESUME\_MODE bit in the USB\_POWER register. This will initiate a remote wakeup. When this bit is set, the USB controller exits suspend mode and drives resume signaling onto the bus. The processor core should clear this bit after 10 ms (a maximum of 15 ms) to end resume signaling.

**NOTE:** No Resume interrupt will be generated when the software initiates remote wakeup.

No RESUME\_B interrupt is generated when suspend mode is exited by the processor core.

## Start-of-frame (SOF) Packets

When the USB controller is operating in peripheral mode, it should receive a start-of-frame packet from the host every millisecond when in full-speed mode, or every 125 microseconds when in high-speed mode.

When the SOF packet is received, the 11-bit frame number contained in the packet is written into the USB\_FRAME register and an output pulse, lasting one USB clock bit period, is generated on SOF\_PULSE (internal USB controller signal). A SOF\_B interrupt is also generated (if enabled in the USB\_INTRUSBE register).

After the USB controller has started to receive SOF packets, the controller expects one every millisecond (or 125 ms when in high-speed mode). If no SOF packet is received after 1.00358 ms (or 125.125 ms), it is assumed that the packet is lost. An SOF\_PULSE (together with a SOF\_B interrupt, if enabled) is still generated though the USB\_FRAME register is not updated. The USB controller continues to generate an SOF\_PULSE every millisecond (or 125 ms) and re-synchronizes these pulses to the received SOF packets when these packets are successfully received again.

## Soft Connect/Soft Disconnect

In peripheral mode, the USB controller can be programmed to switch between normal mode and non-driving mode by setting or clearing the SOFT\_CONN bit of the USB\_POWER register. When this SOFT\_CONN bit is set to 1, the USB controller is placed in its normal mode and the D+/D- lines of the USB bus are enabled. When the SOFT\_CONN bit is zero, the PHY is put into non-driving mode and D+ and D- are three-stated. The USB controller appears to have been disconnected from the USB bus.

After system reset, SOFT\_CONN is cleared to 0. From that point, the USB controller appears disconnected until the software has set SOFT\_CONN to 1. The application software can then choose when to set the PHY to its normal mode. Systems with a lengthy initialization procedure may use this to ensure that initialization is complete and the system is ready to perform enumeration before connecting to the USB. Once the Soft Conn bit has been set to 1, the software can also simulate a disconnect by clearing this bit to 0.

## Error Handling As a Peripheral

A control transfer may be aborted due to a protocol error on the USB, the host prematurely ending the transfer, or if the function controller software wishes to abort the transfer (for example, because it cannot process the command).

The USB controller will automatically detect protocol errors and send a STALL packet to the host under the following conditions:

1. The host sends more data during the OUT data phase of a write request than was specified in the command. This condition is detected when the host sends an OUT token after the DataEnd bit is set.
2. The host requests more data during the IN data phase of a read request than was specified in the command. This condition is detected when the host sends an IN token after the DataEnd bit in the USB\_CSR0 register is set.
3. The host sends more than *MaxPktSize* data bytes in an OUT data packet.
4. The host sends a non-zero length DATA1 packet during the status phase of a read request.

When the USB controller has sent the STALL packet, it sets the SentStall bit and generates an interrupt. When the software receives an Endpoint 0 interrupt with the SentStall bit set, it should abort the current transfer, clear the SentStall bit, and return to the IDLE state.

If the host prematurely ends a transfer by entering the status phase before all the data for the request is transferred, or by sending a new SETUP packet before completing the current transfer, then the SetupEnd bit will be set and an Endpoint 0 interrupt generated. When the software receives an Endpoint 0 interrupt

with the `SetupEnd` bit set, it should abort the current transfer, set the `ServicedSetupEnd` bit, and return to the IDLE state. If the `RxPktRdy` bit is set, this indicates that the host has sent another SETUP packet and the software should then process this command.

If the software wants to abort the current transfer, because it cannot process the command or has some other internal error, then it should set the `SendStall` bit. The USB controller will then send a STALL packet to the host, set the `SentStall` bit and generate an Endpoint 0 interrupt.

## Stalls Issued to Control Transfers

In peripheral mode, the USB controller automatically issues a STALL handshake to a control transfer under the following conditions:

1. The host sends more data during an OUT data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the host sends an OUT token (instead of an IN token) after the processor core has unloaded the last OUT packet and set `DATAEND`.
2. The host requests more data during an IN data phase of a control transfer than was specified in the device request during the SETUP phase. This condition is detected by the USB controller when the host sends an IN token (instead of an OUT token) after the processor core has cleared `TXPKTRDY` and set `DATAEND` in response to the ACK issued by the host to what should have been the last packet.
3. The host sends more than *MaxPktSize* data with an OUT data token.
4. The host sends the wrong PID (packet identifier) for the OUT status phase of a control transfer.
5. The host sends more than a zero length data packet for the OUT status phase.

## Zero Length OUT Data Packets in Control Transfers

A zero-length OUT data packet is used to indicate the end of a control transfer. In normal operation, such packets should only be received after the entire length of the device request is transferred (for example, after the processor core has set `DATAEND`). If the host sends a zero-length OUT data packet before the entire length of device request is transferred, this packet signals the premature end of the transfer. In this case, the USB controller automatically flushes any IN token loaded by processor core ready for the data phase from the FIFO and sets `SETUPEND`.

## USB Host Mode

USB OTG interface operations in host mode differ from peripheral mode in a number of ways. The following sections describe host mode operations.

## Transaction Scheduling

When operating as a host, the USB controller maintains a frame counter. If the target function is a full-speed device, the USB controller automatically sends an SOF packet at the start of each frame or micro-frame. If the target function is a low-speed device, a K state is transmitted on the bus to act as a *keep-alive* to stop the low-speed device from going into suspend mode.

After the SOF packet is transmitted, the USB controller cycles through all the endpoints looking for active transactions. An active transaction is defined as an RX endpoint for which the REQPKT\_H bit is set or a TX endpoint for which the TXPKTRDY bit is set.

An active isochronous or interrupt transaction will only start if it is found on the first transaction scheduler cycle of a frame and if the interval counter for that endpoint has counted down to zero. This ensures that only one interrupt or isochronous transaction occurs per endpoint per  $n$  frames/micro frames (or up to three if high-bandwidth support is selected) where  $n$  is the interval set in the USB\_TXINTERVAL or USB\_RXINTERVAL register for that endpoint.

An active bulk transaction is started immediately, provided there is sufficient time left in the frame to complete the transaction before the next SOF packet is due. If the transaction needs to be retried (for example, because a NAK was received or the target function did not respond) then the transaction is not retried until the transaction scheduler has checked all the other endpoints for active transactions first. This check ensures that an endpoint that is sending a lot of NAKs does not block other transactions on the bus. The USB controller lets you specify a limit (USB\_TXINTERVAL or USB\_RXINTERVAL registers) to the length of time in which NAKs may be received from a particular target before the endpoint is timed out.

## Endpoint Setup and Data Transfer

When the HOST\_MODE bit is set to 1, the USB controller operates as a host for point-to-point communications with another USB device or, when attached to a hub, for communication with a whole range of devices in a multi-point set-up. High-speed, full-speed and low-speed USB functions are supported, both for point-to-point communication and for operation through a hub. (Where necessary, the core automatically carries out the necessary transaction translation needed to allow a low-speed or full-speed device to be used with a USB 2.0 hub.)

Control, Bulk, Isochronous or Interrupt transactions are supported.

Transfers between the subsystem and endpoint FIFOs in host mode are similar to peripheral mode. With this in mind, see many of the descriptions of processor core to FIFO data transfer in [USB Peripheral Mode](#).

## Control Transaction as a Host

Host control transactions are conducted through Endpoint 0. The software is required to handle all the Standard Device Requests that may be sent or received through Endpoint 0 (as described in *Universal Serial Bus Specification*, Revision 2.0, Chapter 9).

For a USB peripheral, there are three categories of Standard Device Requests to be handled: Zero Data Requests (in which all the information is included in the command), Write Requests (in which the

command will be followed by additional data), and Read Requests (in which the device is required to send data back to the host).

Zero Data Requests comprise a SETUP command followed by an IN status phase.

Write Requests comprise a SETUP command, followed by an OUT data phase followed by an IN status phase.

Read Requests comprise a SETUP command, followed by an IN data phase followed by an OUT status phase.

A timeout may be set to limit the length of time during which the USB controller will retry a transaction that is continually NAKed by the target. This limit can be between 2 and  $2^{15}$  frames/micro frames and is set through the `USB_NAKLIMIT0` register.

The following sections look at the steps in different phases of a control transaction to describe the actions of the core in issuing Standard Device Requests.

## Setup Phase as a Host

The processor core driving the host device performs the following actions for the SETUP phase of a control transaction.

1. Load the eight bytes of the required device request command into the Endpoint 0 FIFO
2. Set `SETUPPKT_H` (bit 3) and `TxPtdRdy` (bit 1) of the `USB_CSR0` register. These bits must be set together.

The USB controller then sends a SETUP token followed by the 8-byte command to Endpoint 0 of the addressed device, retrying as necessary.

3. At the end of the attempt to send the data, the USB controller will generate an Endpoint 0 interrupt (for example, set `IntrTx.D0`). The processor core should then read `USB_CSR0` to establish whether the `STALL_RECEIVED_H` bit, the `ERROR_H` bit or the `NAK_TIMEOUT_H` bit is set.

If `STALL_RECEIVED_H` is set, it indicates that the target did not accept the command (for example, because it is not supported by the target device) and so has issued a STALL response.

If `ERROR_H` is set, it means that the USB controller has tried to send the SETUP packet and the following data packet three times without getting a response.

If `NAK_TIMEOUT_H` is set, it means that the USB controller has received a NAK response to each attempt to send the SETUP packet, for longer than the time set in the `USB_NAKLIMIT0` register. The USB controller can then be directed either to continue trying this transaction (until it times out again) by clearing the `NAK_TIMEOUT_H` bit or to abort the transaction by flushing the FIFO before clearing the `NAK_TIMEOUT_H` bit.

4. If none of `STALL_RECEIVED_H`, `ERROR_H` or `NAK_TIMEOUT_H` is set, the SETUP phase is correctly acknowledged and the processor core should proceed to the following IN data phase, OUT data phase or IN status phase specified for the particular Standard Device Request.

## IN Data Phase as a Host

The processor core driving the host device performs the following actions for the IN data phase of a control transaction.

1. Set REQPKT\_H in USB\_CSR0.
2. Wait while the USB controller sends the IN token and then receives the required data back.
3. When the USB controller generates the Endpoint 0 interrupt (for example, by setting EPO\_TX in the USB\_INTRTX register)-read USB\_CSR0 to establish whether the STALL\_RECEIVED\_H bit, the ERROR\_H bit, the NAK\_TIMEOUT\_H bit or RxPktRdy is set.

If STALL\_RECEIVED\_H is set, it indicates that the target has issued a STALL response.

If ERROR\_H is set, it means that the USB controller has tried to send the required IN token three times without getting a response.

If NAK\_TIMEOUT\_H is set, it means that the USB controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the USB\_NAKLIMIT0 register. The USB controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK\_TIMEOUT\_H bit; or to abort the transaction by clearing REQPKT\_H before clearing the NAK\_TIMEOUT\_H bit.

4. If RxPktRdy is set, the processor core should read the data from the Endpoint 0 FIFO, then clear RxPktRdy.
5. If further data is expected, the processor core should repeat the previous steps.

When all the data is successfully received, the processor core should proceed to the OUT status phase of the control transaction.

## OUT Data as a Host (Control)

The processor core driving the host device performs the following actions for the OUT data phase of a control transaction.

1. Load the data to be sent into the Endpoint 0 FIFO
2. Set the TxPktRdy bit in USB\_CSR0.

The USB controller then proceeds to send an OUT token followed by the data from the FIFO to Endpoint 0 of the addressed device, retrying as necessary.

3. At the end of the attempt to send the data, the USB controller will generate an Endpoint 0 interrupt (for example, set EPO\_TX in USB\_INTRTX register). The processor core should then read USB\_CSR0 to estab-

lish whether the `STALL_RECEIVED_H` bit (D2), the `ERROR_H` bit (D4) or the `NAK_TIMEOUT_H` bit (D7) is set.

If `STALL_RECEIVED_H` is set, it indicates that the target has issued a `STALL` response.

If `ERROR_H` is set, it means that the USB controller has tried to send the `OUT` token and the following data packet three times without getting a response.

If `NAK_TIMEOUT_H` is set, it means that the USB controller has received a `NAK` response to each attempt to send the `OUT` token, for longer than the time set in the `USB_NAKLIMIT0` register. The USB controller can then be directed either to continue trying this transaction (until it times out again) by clearing the `NAK_TIMEOUT_H` bit; or to abort the transaction by flushing the FIFO before clearing the `NAK_TIMEOUT_H` bit.

If none of `STALL_RECEIVED_H`, `ERROR_H` or `USB_NAKLIMIT0` is set, the `OUT` data is correctly acknowledged.

4. If further data needs to be sent, the processor core should repeat the previous steps.

When all the data is successfully sent, the processor core should proceed to the `IN` status phase of the control transaction.

## IN Status Phase as a Host (Following `SETUP` Phase or `OUT` Data Phase)

The processor core driving the host device performs the following actions for the `IN` status phase of a control transaction.

1. Set `STATUSPKT_H_H` and `REQPKT_H` (bits 6 and 5 of `USB_CSR0`, respectively). These bits must be set together.
2. Wait while the USB controller both sends an `IN` token and receives a response from the USB peripheral.
3. When the USB controller generates the Endpoint 0 interrupt (for example, sets `EP0_TX` in `USB_INTRTX` register), read `USB_CSR0` to establish whether the `STALL_RECEIVED_H` bit, the `ERROR_H` bit, the `NAK_TIMEOUT_H` bit or `RxPktRdy` is set.

If `STALL_RECEIVED_H` is set, it indicates that the target could not complete the command and so has issued a `STALL` response.

If `ERROR_H` is set, it means that the USB controller has tried to send the required `IN` token three times without getting a response.

If `NAK_TIMEOUT_H` is set, it means that the USB controller has received a `NAK` response to each attempt to send the `IN` token, for longer than the time set in the `USB_NAKLIMIT0` register. The USB controller can then be directed either to continue trying this transaction (until it times out again) by clearing the `NAK_TIMEOUT_H` bit or to abort the transaction by clearing `REQPKT_H` and `STATUSPKT_H_H` before clearing the `NAK_TIMEOUT_H` bit.

4. If `RxPktRdy` is set, the processor core should simply clear `RxPktRdy`.

## OUT Status Phase as a Host (following IN Data Phase)

The processor core driving the host device performs the following actions for the OUT status phase of a control transaction.

1. Set STATUSPKT\_H and TxPktRdy bits. These bits must be set together.
2. Wait while the USB controller both sends the OUT token and a zero-length DATA1 packet.
3. At the end of the attempt to send the data, the USB controller will generate an Endpoint 0 interrupt. The processor core should then read USB\_CSR0 to establish whether the STALL\_RECEIVED\_H bit, the ERROR\_H bit or the NAK\_TIMEOUT\_H bit is set.

If STALL\_RECEIVED\_H is set, it indicates that the target could not complete the command and so has issued a STALL response.

If ERROR\_H is set, it means that the USB controller has tried to send the STATUS packet and the following data packet three times without getting a response.

If NAK\_TIMEOUT\_H is set, it means that the USB controller has received a NAK response to each attempt to send the IN token, for longer than the time set in the USB\_NAKLIMIT0 register. The USB controller can then be directed either to continue trying this transaction (until it times out again) by clearing the NAK\_TIMEOUT\_H bit or to abort the transaction by flushing the FIFO before clearing the NAK\_TIMEOUT\_H bit.

4. If none of STALL\_RECEIVED\_H, ERROR\_H or NAK\_TIMEOUT\_H is set, the status phase is correctly acknowledged.

## Host IN Transactions

When the USB controller operates as a host, IN transactions are handled like OUT transactions are handled when the USB controller is operating as a peripheral. But the transaction must first be initiated by setting the REQPKT\_H bit in USB\_RXCSR. This bit indicates to the transaction scheduler that there is an active transaction on this endpoint. The transaction scheduler then sends an IN token to the target function.

When the packet is received and placed in the RX FIFO, the RXPkTRDY bit in USB\_RXCSR is set, and the appropriate RX endpoint interrupt is generated (if enabled) to signal that a packet can now be unloaded from the FIFO. When the packet is unloaded, RXPkTRDY is cleared. The AUTOCLEAR\_R bit in the USB\_RXCSR register can be used to have RXPkTRDY automatically cleared when a maximum sized packet is unloaded from the FIFO. There is also an AUTOREQ\_RH bit in USB\_RXCSR that causes the REQPKT\_H bit to be automatically set when the RXPkTRDY bit is cleared. The AUTOCLEAR\_R and AUTOREQ\_RH bits can be used with an external DMA controller to perform complete bulk transfers without processor core intervention.

If the target function responds to a bulk or interrupt IN token with a NAK, the USB controller keeps retrying the transaction until the NAK limit set (in USB\_NAKLIMIT0) is reached. If the target function responds with a STALL, the USB controller does not retry the transaction, but does interrupt the processor core with the RXSTALL\_TH bit in the USB\_RXCSR register set. If the target function does not respond to the IN token within the required time (or there was a CRC or bit-stuff error in the packet), the USB controller

retries the transaction. If after three attempts the target function still has not responded, the USB controller clears the REQPKT\_H bit and interrupts the processor core with the DATAERROR\_R bit in USB\_RXCSR set.

## Host OUT Transactions

When the USB controller operates as a host, OUT transactions are handled in a similar manner to the way IN transactions are handled when the USB controller operates as a peripheral.

The TXPKTRDY bit in the USB\_TXCSR register needs to be set as each packet is loaded into the TX FIFO and the AUTOSET\_T bit in USB\_TXCSR can be used to cause the TXPKTRDY bit to be automatically set when a maximum sized packet is loaded into the FIFO. The AUTOSET\_T bit can be used with an external DMA controller to perform complete bulk transfers without processor core intervention.

If the target function responds to the OUT token with a NAK, the USB controller keeps retrying the transaction until the NAK limit set in USB\_NAKLIMIT0 is reached. If the target function responds with a STALL, the USB controller does not retry the transaction, but does interrupt the processor core with the RXSTALL\_TH bit in the USB\_TXCSR register set. If the target function does not respond to the OUT token within the required time (or there was a CRC or bit-stuff error in the packet), the USB controller retries the transaction. If after three attempts the target function still has not responded, the USB controller flushes the FIFO and interrupts the processor core with the ERROR\_TH bit in USB\_TXCSR set.

## Multi-point Support

The following sections describe the controller's multi-point support

### Allocating Devices to Endpoints

The separate functions of the connected devices are allocated to the endpoints within the USB controller through a group of three registers, which are associated with each Rx or Tx endpoint implemented (including Endpoint 0).

The registers concerned are Tx/RxFuncAddr, Tx/RxHubAddr and Tx/RxHubPort. (The location of these registers depends on which of the endpoints is being addressed.)

The information that needs to be recorded in the Tx/RxFuncAddr register is the address of the target function that is to be accessed through the selected endpoint. This information needs to be recorded separately for each Tx and Rx endpoint that is used. In particular, both TxFuncAddr and RxFuncAddr need to be set for Endpoint 0.

The Tx/RxHubAddr and Tx/RxHubPort registers are provided for the case where a full- or low-speed device is connected to the USB controller via a high-speed USB 2.0 hub, which carries out the required transaction translation between high-speed transmission and low-/full-speed transmission. Where this is the case, the Tx/RxHubAddr and Tx/RxHubPort registers need to record the address of the hub that carries out the transaction translation and the port of that hub through which the associated Tx/Rx endpoint needs to access the device. Note that if Endpoint 0 is connected to a hub, then both the Tx and the Rx versions of these registers need to be set for this endpoint. The Tx/RxHubAddr register is further

used to record whether the hub offers multiple transaction translators or just a single transaction translator. This has a significant effect on the overall bandwidth that can be achieved.

In addition to recording the address of the target function through these three registers, the endpoint number and operating speed of the target device and the type of transaction that will be executed need to be recorded. For a Tx endpoint, this information needs to be set in the TxType register when the Index register is set to select the required endpoint. For an Rx endpoint, this information needs to be set in the RxType register when the Index register is set to select the required endpoint. In both cases, the endpoint number is recorded in bits D3 – D0, the transaction type is selected through bits D5 – D4, and the operating speed is selected through bits D7 – D6.

In the case of Endpoint 0, just the speed needs to be set (this endpoint only having the facilities to handle Control transactions and therefore always being associated with a device Endpoint 0). This speed setting is made through bits D7 – D6 of the Type 0 register, which is located at 1Ah when the Index register is set to 0.

## Multi-point Operation

Once the allocation of functions to endpoints has been made and the operating speed of the target device recorded, as described above, most operations in a Multi-point set-up are no different from those for the equivalent actions where the core is attached to a single other device.

However, additional steps are required:

- Where the option of dynamically switching the allocation of functions to endpoints is taken (for example to allow a wider range of devices to be supported)
- Where the control packets normally associated with Endpoint 0 are handled through a different endpoint.

If dynamic allocation is used, it becomes essential for the user to keep track of the current data toggle state associated with the endpoint and with each of the devices that are allocated to that endpoint. Knowledge of this state is necessary to allow the user to select the correct data toggle state when the switch is made between one device and other. (This action is the programs responsibility because the core cannot determine what data toggle state is expected when a function is being switched in and out of use.)

The data toggle state can be switched from its current state by writing to the appropriate TxCSRL/RxCSRL register to set the Data Toggle Write Enable and Data Toggle bits that are included in these registers when the core is in Host mode.

Data Toggle Write Enable and Data Toggle bits are also included in CSR0 when the core is operating in Host mode. However, Control operations carried out through the core's Endpoint 0 should normally always leave the data toggle in the expected state.)

Where control packets are handled through an endpoint other than Endpoint 0, the user has additionally to prompt for each Setup token to be sent. This involves setting the SetupPkt bit that is included in the TxCSR register when the core is operating in Host mode, alongside the TkPktRdy bit. If the SetupPkt bit is not set, an OUT token will be sent.

Overall, the recommendation is to use the controller's Endpoint 0 to handle Control packets for all of the devices attached to the controller, and to switch the allocation of this endpoint as appropriate. The issue of sending the correct token is then taken care of, as is the issue of ensuring that the data toggle is correctly set for this endpoint.

Using a different endpoint for this function is possible, as described above, but there are further points to note:

- The control function must be allocated to an Rx/Tx endpoint pair (i.e. with the same endpoint number).
- The chosen endpoints must each be associated with FIFOs that can accommodate the packet size associated with EP0 transactions at the chosen operating speed which can be a minimum of 8 bytes for low- or full-speed transactions but 64 bytes for high-speed transactions.

## Multi-point Bandwidth Considerations

The ability of a multi-point system to cope with isochronous transactions, in particular, is determined by the available bandwidth.

Once an endpoint has been set up, all scheduling is handled in hardware. However, as with PC-based EHCI/OHCI/UHCI hosts, before opening a periodic pipe (for use by isochronous or interrupt traffic), software must determine that there is sufficient bandwidth available. Further, if the periodic pipe is opened to a full-speed device through a high-speed hub, software must confirm that sufficient bandwidth is available both on the local high-speed bus and the full-speed bus generated by the transaction translator in the hub. The bandwidth required for different transactions can be determined using similar algorithms to those used in connection with PC-based hosts (detailed in Section 5.11.3 of the USB 2.0 Specification).

As would be expected, the bandwidth available will be greater where the hub used supports multiple transaction translators.

## Babble Interrupt

If the bus is still active at the end of a frame, the USB controller assumes that the function it is connected to has malfunctioned, suspends all transactions, and generates a babble interrupt (`RESET_OR_BABLE_B`). The USB controller does not start a transaction until the bus is inactive for at least the minimum inter-packet delay. The controller also does not start a transaction unless it can be finished before the end of the frame.

To recover from a babble error condition, the processor must take the following actions inside the interrupt service routine.

1. Turn off VBUS. Wait until the VBUS level indicator reads b#01.
2. Turn on VBUS. Wait until the VBUS level indicator reads b#11.
3. Set the SESSION bit

The VBUS level indicator is a field of the USB\_OTG\_DEV\_CTL register.

**NOTE:** Because VBUS is sourced external to the processor, make sure that in your hardware design you connect a GPIO or the dedicated `DrvVBUS` signal to the external source so that you can use software to turn VBUS on and off.

## VBUS Events

The USB On-The-Go specification defines a series of thresholds to which the devices involved in point-to-point communications are required to respond.

- VBUS Valid (required to be between 4.4V and 4.75V)
- Session Valid for A device (required to be between 0.8V and 2.1V)
- Session End (required to be between 0.2V and 0.8V)

Which thresholds are critical and the processor response depends upon whether the device is an A device or a B device and the circumstances of the event. These actions are described below.

### Actions as an “A” Device

VBUS >VBUS Valid with session initiated by USB controller (that is, VBUS level indicator = b#11 and session bit is set). When VBUS is greater than VBUS Valid, the USB controller selects Host Mode and waits for a device to be connected. It then generates a connect interrupt. The processor resets and enumerates the connected B device.

VBUS> Session Valid with session initiated by B device (that is, VBUS level indicator = b#10 and session bit is clear). When VBUS is greater than Session Valid, the USB controller generates a session request interrupt. The processor sets the session bit and the USB controller either stays in Host mode or changes to Peripheral mode, depending upon the state of the pull-up resistor on the B device. For more information, refer to the Host Negotiation Protocol of the OTG specification. The selected mode is indicated by the state of the Host Mode bit.

VBUS below VBUS Valid while the Session bit remains set (that is, VBUS level indicator b#11 and session bit is set). This indicates a problem with the VBUS power level. For example, the battery power may have dropped too low to sustain VBUS Valid. Or, the B device may be drawing more current than the A device can provide. In either case, the USB controller will automatically terminate the session and generate a VBUS error interrupt.

To recover from this VBUS error condition, the processor must take the following actions inside the VBUS error interrupt handler.

- Turn off VBUS Wait until the VBUS level indicator reads b#01.
- Turn on VBUS Wait until the VBUS level indicator reads b#11.
- Set the SESSION bit

The VBUS level indicator is a field of the USB\_OTG\_DEV\_CTL register.

**NOTE:** Because VBUS is sourced external to the processor, make sure that in your hardware design you connect a GPIO or the dedicated `DrvVBUS` signal to the external source so that you can use software to turn VBUS on and off.

## Actions as a “B” Device

`VBUS > Session Valid` (that is, VBUS level indicator = b#10 and session bit is clear). This indicates activity from the A device. The USB controller sets the session bit and disconnects the pull down resistor on the D+ line.

`VBUS < Session Valid` while the session bit remains set (that is, VBUS level indicator = b#01 and session bit is set). This indicates that the A device has lost power (or become disconnected). The USB controller clears the session bit and generates a disconnect interrupt. The processor ends the session.

`VBUS < Session End` (that is, VBUS level indicator = b#00). This is the condition under which a B device can initiate a session request. If the session bit is set, then after 2ms of SE0 on the bus, the USB controller starts SRP by first pulsing the data line, then pulsing VBUS.

## Host Mode Reset

If the `RESET` bit in the `USB_POWER` register is set while the USB controller is in host mode, the USB controller generates reset signaling on the bus. The processor core should keep this bit set for 20 ms to ensure correct resetting of the target device. After the processor core has cleared the bit, the USB controller starts its frame counter and transaction scheduler.

## Host Mode Suspend

**Entry into Suspend mode.** When operating as a host, the USB controller can be prompted to go into Suspend mode by setting the Suspend Mode bit in the Power register. When this bit is set, the USB controller completes the current transaction then stops the transaction scheduler and frame counter. No further transactions are started and no SOF packets are generated. If the `Enable SuspendM` bit is set, the UTMI+ PHY will go into low-power mode when the USB controller goes into Suspend mode and stop XCLK.

**Sending Resume Signaling.** When the application requires the USB controller to leave Suspend mode, it needs to clear the Suspend bit in the Power register, set the Resume bit and leave it set for 20ms. While the Resume bit is high, the USB controller will generate Resume signaling on the bus. After 20 ms, the processor core should clear the Resume bit, at which point the frame counter and transaction scheduler will be started.

**Responding to Remote Wake-up.** If Resume signaling is detected from the target while the USB controller is in Suspend mode, the UTMI+ PHY will be brought out of low-power mode and restart XCLK. The USB controller will then exit Suspend mode and automatically set the Resume bit in the Power register to ‘1’ to take over generating the Resume signaling from the target. If the Resume interrupt is enabled, an interrupt will be generated.

## Suspending and Resuming the Controller

With the introduction of Link Power Management, there are two basic methods for the USB controller to be suspended and resumed. These two methods are demonstrated in the basic LPM transaction diagram shown below.

**Figure 22-9:** Basic LPM Transaction

The procedure in which the USB controller is suspended and resumed depends on whether the core is operating as a device or a host and the method of suspend desired. These options are described in the following sections.

### Suspend/Resume By Inactivity On The USB Bus (L0 To L2 State) In Peripheral Mode

The following steps occur in this mode.

1. Entry into Suspend mode. When operating as a peripheral, the USB controller monitors activity on the USB and when no activity has occurred for 3 ms, it goes into Suspend mode. If the Suspend interrupt has been enabled, an interrupt will be generated at this time. The SUSPENDM output will also go low (if enabled).

At this point, the POWERDWN signal is also asserted to indicate that the application may save power by stopping CLK. POWERDWN then remains asserted until either power is removed from the bus (indicating that the device has been disconnected) or Resume signaling or Reset signaling is detected on the bus.

2. When Resume signaling occurs on the bus, first CLK must be restarted if necessary. The USB controller will then automatically exit Suspend mode. If the Resume interrupt is enabled, an interrupt will be generated.
3. Initiating a Remote Wakeup. If the software wants to initiate a remote wakeup while the controller is in Suspend mode, it should write to the USB\_Power register to set the Resume bit 2 to 1. (Note: If CLK has been stopped, it will need to be restarted before this write can occur.) The software should leave

then this bit set for approximately 10 ms (minimum of 2 ms, a maximum of 15 ms) before resetting it to 0. By this time the hub should have taken over driving Resume signaling on the USB.

**NOTE:** No Resume interrupt will be generated when the software initiates a remote wakeup.

### **Suspend/Resume By Inactivity On The USB Bus (L0 To L2 State) In Host Mode**

The following steps occur in this mode.

1. Entry into Suspend mode. When operating as a host, the USB controller can be prompted to go into Suspend mode by setting the Suspend Mode bit in the Power register. When this bit is set, the USB controller will complete the current transaction then stop the transaction scheduler and frame counter. No further transactions will be started and no SOF packets will be generated. If the Enable SuspendM bit (Power.D0) is set, the UTMI+ PHY will go into low-power mode when the controller goes into Suspend mode and stop XCLK.
2. Sending Resume Signaling. When the application requires the controller to leave Suspend mode, it needs to clear the Suspend bit in the Power register, set the Resume bit and leave it set for 20 ms. While the Resume bit is high, the controller will generate Resume signaling on the bus. After 20 ms, the processor core should clear the Resume bit, at which point the frame counter and transaction scheduler will be started.
3. Responding to Remote Wake-up. If Resume signaling is detected from the target while the USB controller is in Suspend mode, the UTMI+ PHY will be brought out of low-power mode and restart XCLK. The controller will then exit Suspend mode and automatically set the Resume bit in the USB\_Power register to 1 to take over generating the Resume signaling from the target. If the Resume interrupt is enabled, an interrupt will be generated.

### **Suspend/Resume By an LPM Transaction (L0 To L1 State) In Peripheral Mode**

The following steps occur in this mode.

1. Entry into Suspend mode. When operating as a peripheral, the controller will never initiate an LPM Suspend (transition from the L0 state to the L1 state). Rather, the controller will only Suspend at the request of the host. However, for this to occur, the LPM feature must be enabled by setting up the LPM\_CNTRL register (address 0x362) appropriately. The register field LPMEN (in the LPM\_CNTRL register) is used to enable and support extended and LPM transactions. The LPMXMT field is used instruct the hardware that it is ready to suspend and to respond to the next LPM transaction with an

ACK. In this case, the controller will respond to the next LPM transaction with an ACK if all other conditions are met. The response to an LPM transaction by the controller is summarized below:

**Table 22-6:** Response to LPM Transaction

| LPMXMT                        | LPMCNTL                           | Data Pending (Resides in Tx FIFOs) | Response to Next LPM Transaction |
|-------------------------------|-----------------------------------|------------------------------------|----------------------------------|
| 1'b0,<br>1'b0<br>1'b1<br>1'b1 | 2'b00,<br>2'b10<br>2'b00<br>2'b10 | Don't Care                         | Timeout                          |
| 1'b0,<br>1'b1                 | 2'b01                             | Don't Care                         | STALL                            |
| 1'b0                          | 2'b11                             | Don't Care                         | NYET                             |
| 1'b1                          | 2'b11                             | Yes                                | NYET                             |
| 1'b1                          | 2'b11                             | No                                 | ACK                              |

For all cases shown above in which the controller responds (No timeout occurs), an LPM interrupt will be generated in the LPM\_INTR register. Note that the controller will respond with an ACK only if there is no data pending in any of the TX Endpoint fifos. If there is data pending, the USB controller will respond with a NYET.

Once an LPM transaction is successfully received three events will occur:

- The LPM\_ATTR register (address 0x360) will be updated with values received in the LPM transaction just received. The LPM\_ATTR register contains the following fields:

**LinkState** - This field tells the controller what state to transition to. The only valid value for this field is 4'h1 indicating that the core should suspend. For any other value, the MUSBMHDCR will respond with a STALL and the appropriate interrupt will be generated. However, in this case the LPM\_ATTR register will be updated so that software can observe the non compliant LPM packet payload. In addition, the LPMERR interrupt will also be generated informing software of the non-compliant LPM transaction.

**HIRD** - This field tells the controller the minimum duration that the host will drive resume signaling on the bus. This field represents a resume duration range from 50us to 1200us. This value may be different for subsequent LPM transactions.

**RmtWak** - This is a 1 bit field indicating if the remote wakeup by the controller is allowed. This bit only applies to the current suspend/resume cycle only. This bit may be different for subsequent LPM transactions. This bit should not supersede the wakeup capability that was previously negotiated on enumeration of the controller.

- b. The controller will suspend 9us after transmitting the ACK. Resume signaling can be driven by the Host or the controller 50us after this event. During this 9us interval, the host may continue to transmit the LPM transaction. The controller will respond with an ACK in this case regardless of the LPMXMT value in the LPM\_CNTRL register.
- c. An interrupt will be generated informing software of the response (An ACK in this case). An ACK response is the indication to software that the controller has suspended.

Since the primary purpose of LPM is to save power, the software will read the LPM\_ATTR register to determine the attributes of the Suspend. Software must make a determination based on these attributes whether additional power savings in the system can be exploited. In making this determination it is noted that if the host initiates the resume signaling, the controller will be required to respond to packet transmissions within the time specified by HIRD + 10 us.

2. When resume signaling occurs on the Bus When the host resumes the bus, it will drive resume signaling for a minimum time specified by the HIRD field in the LPM\_ATTR register. The controller must be able to respond to traffic within the time HIRD + 10us. The controller will transition to a normal operating state automatically and a resume interrupt will be generated in the LPM\_INTR register. However for this to occur, the inputs CLK and XCLK must be available. To facilitate the resume timing requirement, an additional feature, LPMNAK, is provided in the LPM\_CNTRL register. If LPMNAK is set to 1'b1, all endpoints will respond to any transaction (other than an LPM) with a NAK. This bit will only take effect after the controller has LPM suspended. Typically, this bit would be asserted when the LPMXMT field is also asserted. Using this feature may simplify the resume timing requirement because only XCLK is needed for the controller to respond (with a NAK) to traffic. Software can continue to restore the system to normal operation while the controller responds to all transactions with a NAK. After the system has been completely restored, software can then clear the LPMNAK field in the LPM\_CNTRL register.
3. Initiating remote wakeup. If the software wants to initiate a remote wakeup while the controller is in Suspend mode, it should write a 1'b1 to the LPMRES bit in the LPM\_CNTRL register. This bit is self clearing. Writing a 1'b1 will cause resume signaling to be driven on the bus for 50us. The host will respond by driving resume for 60us to 990us. 10 us after the host stops driving resume, the controller will transition to its normal operational state and will be ready for packet transmission. A Resume interrupt will be generated in the LPM\_INTR register.

### **Suspend/Resume by an LPM Transaction (L0 to L1 State) in Host Mode**

The following steps occur in this mode.

1. Entry into Suspend mode. When operating as a host, the controller will initiate an LPM Suspend (transition from the L0 state to the L1 state) by initiating an LPM transaction as follows:
  - a. Software will set-up the desired attributes of the Suspend in the LPM\_ATTR register (address 0x360). Enabling remote wakeup and a large HIRD will give the peripheral more opportunity to conserve power.
  - b. All LPM interrupts should be enabled in the LPM\_INTEN register.

- c. Software should initiate the transaction by writing a 0x01 to the LPM\_CNTRL register.
- d. An interrupt is generated to inform software of the response to the LPM transaction. If an ACK was received, then the controller will suspend automatically within 8us. This is the indication that the controller has suspended.

If the response from the device has a bit stuff error or a PID error, then an LPMERR interrupt is generated. The hardware will immediately attempt the LPM transaction two more times. The device will not suspend for 8us after the initial LPM so it will be able to respond to either of these subsequent LPM transactions. If an LPM timeout has occurred three times, the LPMNC and the LPMERR interrupts will be set. At this time, software is unaware of the device state and must deduce it by other means.

2. Sending Resume Signaling. Resume signaling should be generated by software as follows:
  - a. All LPM interrupts should be enabled in the LPM\_INTEN register.
  - b. Software should write the LPMRES bit in the LPM\_CNTRL register. This bit is self-clearing. This will cause resume signaling to be generated on the Bus for the time that is currently specified in the HIRD field in the LPM\_ATTR register. It is assumed by hardware that this value was used in the last LPM transaction that caused the Suspend.
  - c. After HIRD + 10us, the controller will transition to its normal operational state and be ready for packet transmission. A resume interrupt will be generated in the LPM\_INTR register.

**NOTE:** Prior to resuming, software must ensure that the system is completely restored from a low power state and that the inputs CLK and XCLK are available.

3. Responding to Remote Wake-up. If the remote wakeup feature was enabled in the LPM transaction that caused the Suspend, then the device may drive resume signaling on the bus. When this occurs, the device will drive resume signaling BUS for 50us. The controller will immediately begin driving resume signaling on the BUS and will do so for 60us. 10us after completion of the resume signaling, the controller will transition to its normal operating state and will be ready for packet transmission. At this time, the resume interrupt is generated in the LPM\_INTR register.

## USB Event Control

The following sections provide information on the use of interrupts, reset and the reporting of errors and interface status.

## USB Interrupt Signals

There are two interrupts generated from the USB Controller:

1.  $\text{INTR\_USB0\_STAT} = !(\text{USB0\_INTRTX} \mid \text{USB0\_INTRRX} \mid \text{USB0\_IRQ} \mid \text{DrvVbusInt}) \mid \text{USB0\_LPM\_IRQ}$
2.  $\text{INTR\_USB0\_DATA} = \text{USB0\_DMA\_IRQ}$

Interrupts can be generated from control endpoint zero under the following conditions

- When a control transaction ends before the end of the data is transferred.
- When a data packet is sent or received from the endpoint 0 FIFOs.

Interrupts can be generated from transmit endpoints (USB\_INTRTX) under the following conditions:

- packet sent from the TX FIFO (host and peripheral mode)
- after three attempts at transmitting a packet with no valid handshake packet received (host mode)

Interrupts can be generated from receive endpoints (USB\_INTRRX) under the following conditions:

- packet received into the RX FIFO (host and peripheral mode)
- when a STALL handshake is received (host mode)
- After three attempts at receiving a packet and no data packet is received (host mode).

Interrupts can be generated from the USB status (USB\_INTRUSB) under the following conditions:

- When VBUS drops below the VBUS valid threshold during a session (A device only).
- When SRP signaling is detected (A device only).
- When device disconnect is detected (host mode).
- When a session ends (peripheral mode).
- Device connection detected (host mode).
- Start-of-frame (SOF)
- Reset signaling detected on USB (peripheral mode).
- Babble detected (host mode).
- In suspend mode when resume signaling detected on USB.
- When suspend signaling is detected (peripheral mode).

Interrupts are generated for the following VBUS control requests by the USB controller:

- drive VBUS greater than 4.4V (Default A device)
- stop driving VBUS
- start charging VBUS (peripheral mode)
- stop charging VBUS
- start discharging VBUS (peripheral mode)
- stop discharging VBUS

## Interrupt Handling

When the processor core is interrupted with a USB interrupt, it needs to read the interrupt status register to determine which endpoint(s) have caused the interrupt and jump to the appropriate routine. If multiple endpoints have caused the interrupt, Endpoint 0 should be serviced first, followed by the other endpoints. A flowchart for the USB Interrupt Service Routine is shown below.

**Figure 22-10:** USB Interrupt Service Routine

## USB Reset Signals

The USB controller includes an active-high synchronous hardware reset sourced from the processor core. Another source of peripheral reset is through the USB, when USB reset signaling is detected on the I/O lines. As dictated by the USB 2.0 Specification, this state is entered when both the D+ and D- inputs are driven low for a period of 2.5s or more (though the reset itself is held for typically greater than 10ms by the USB host).

### USB Reset in Peripheral Mode

When a USB reset is detected, the USB controller performs the following actions:

- `USB_FADDR` register set to zero
- `USB_INDEX` register set to zero
- all endpoint FIFOs flushed
- all control and status registers cleared
- all interrupts enabled
- reset interrupt generated

The `USB_INTRUSB` and `USB_OTG_VBUS_IRQ` registers are not affected by the USB controller reset. These registers are only reset (along with those listed above) during a system reset.

If the `HS_ENABLE` bit in the power register was set, the USB controller also tries to negotiate for high-speed operation. Whether high-speed operation is selected is indicated by `HS_Mode` bit in the Power register.

When the application software receives a reset interrupt, it should close any open pipes and wait for bus enumeration to begin.

### USB Reset in Host Mode

If the Reset bit in the power register is set while the USB controller is in host mode, the controller will generate Reset signaling on the bus. If the `HS_ENABLE` bit in the power register was set, it will also try to negotiate for high-speed operation.

The processor core should keep the Reset bit set for at least 20 ms to ensure correct resetting of the target device. After the processor core has cleared the bit, the USB controller starts its frame counter and transaction scheduler.

High-speed operation is selected by the `HS_MODE` bit

## USB Programming Model

The following sections describe the USB OTG programming model.

## OTG Session Request

In order to conserve power, the USB on-the-go supplement allows VBUS to only be powered up when required and to be turned off when the bus is not in use.

VBUS is always supplied by the A device on the bus. The USB controller determines whether it is the A device or the B device by sampling the `USB_ID` input from the PHY. This signal is pulled low when an A-type plug is sensed (signifying that the USB controller is the A device), but the input is taken high when a B-type plug is sensed (signifying that the USB controller is the B device).

## Starting a Session

When the device containing the USB controller wants to start a session, the processor core must set the `SESSION` bit in the `USB_DEV_CTL` register. The USB controller then enables ID pin sensing. This results in the `USB_ID` input either being taken low if an A-type connection is detected or high if a B-type connection is detected. The `B_DEVICE` bit in the `USB_DEV_CTL` register is also set to indicate whether the USB controller has adopted the role of the A device or the 'B' device.

If the USB controller is the A device: The USB controller then enters host mode (the A device is always the default host), and waits for VBUS to go above the VBUS valid threshold, as indicated when the `VBUS1-0` bits in the `USB_DEV_CTL` register go to 11.

The USB controller then waits for a peripheral to be connected. When a peripheral is detected, a connect interrupt (`CONN_B` bit in `USB_INTRUSB`) is generated (if enabled) and either the `FSDEV` or `LSDEV` bit in the `USB_DEV_CTL` register is set, depending on whether a full-speed peripheral or a low-speed peripheral was detected. The processor core should then reset this peripheral. To end the session, the processor core should clear the `SESSION` bit in `USB_DEV_CTL`.

If the USB controller is the 'B' device: The USB controller requests a session using the session request protocol defined in the USB on-the-go supplement. This is accomplished by setting the `SESSION` bit in the `USB_DEV_CTL` register.

At the end of the session, the `SESSION` bit is cleared - usually by the USB controller but it can also be cleared by the processor core if the application software wishes to perform a software disconnect. For more information, see the description of the `USB_DEV_CTL` register. The USB controller switches on the pull-up resistor on D+. This signals to the A device to end the session.

## Detecting Activity

When the other device of the OTG set-up wants to start a session, it either raises VBUS above the session valid threshold (if it is the 'A' device as indicated by the `VBUS1-0` bits in the `USB_OTG_DEV_CTL` register going to 10), or (if it is the 'B' device) first pulses the data line then pulses VBUS. Depending on which of these actions happens, the USB controller can determine whether it is the 'A' device or the 'B' device in the current set-up and act accordingly.

If VBUS is raised above the session valid threshold, the USB controller is the 'B' device. The USB controller sets the `SESSION` bit in the `USB_OTG_DEV_CTL` register. When reset signaling is detected on the bus, a reset interrupt (`RESET_OR_BABLE_B = 1`) is generated (if enabled) that the processor core should interpret as the start of a session. The USB controller is in peripheral mode at this point as the 'B' device is the default peripheral.

At the end of the session, the 'A' device turns off the power to VBUS. When VBUS drops below the session valid threshold (as indicated by the `VBUS1-0` bits in the `USB_OTG_DEV_CTL` register going to 01), the USB controller detects this and clears the `SESSION` bit to indicate that the session has ended. A disconnect interrupt (`DISCON_B` bit in `USB_INTRUSB`) is also generated (if enabled).

If data line/VBUS pulsing is detected, the USB controller is the 'A' device. The controller generates a `SESSION_REQ_B` interrupt (bit 6 in `USB_INTRUSB`, if enabled) to indicate that the 'B' device is requesting a session. The processor core should then start a session by setting the `SESSION` bit.

## Host Negotiation/Configuration

When the USB controller is the A device (`USB_ID` low, `B_DEVICE`= 0), the controller automatically enters host mode when a session starts.

When the USB controller is the B device (`USB_ID` high, `B_DEVICE`= 1), the controller automatically enters peripheral mode when a session starts. The processor core can request that the USB controller become the host by setting the `HOST_REQ` bit in the `USB_OTG_DEV_CTL` register. This bit can be set either when requesting a session start by setting the `SESSION` bit in `USB_OTG_DEV_CTL` or at any time after a session has started. When the USB controller next enters suspend mode (no activity on the bus for 3 ms), and assuming the `HOST_REQ` bit remains set, the controller enters host mode and begins host negotiation (as specified in the USB OTG supplement), causing the PHY to disconnect the pull-up resistor on the D+ line. This should cause the A device to switch to peripheral mode and to connect its own pull-up resistor. When the USB controller detects this, it generates a connect interrupt (`CONN_B` bit in `USB_INTRUSB`) if this is enabled. The controller also sets the `RESET` bit in the `USB_POWER` register to begin resetting the A device. (The USB controller begins this reset sequence automatically to ensure that reset is started as required within 1 ms of the A device connecting its pull-up resistor). The processor core should wait at least 20 ms, then clear the `RESET` bit and enumerate the A device.

When the USB controller-based B device has finished using the bus, the processor core should put it into suspend mode by setting the `SUSPEND_MODE` bit in the `USB_POWER` register. The A device should detect this and either terminate the session or revert to host mode. If the A device is USB controller-based, it generates a disconnect interrupt (`DISCON_B` bit in `USB_INTRUSB`) if this is enabled.

## Wakeup from Hibernate State

To conserve power when the chip is idle, systems often use power-down modes to shut down power and clocks to various parts of the chip. Hibernate state saves the most power (core clock, peripherals clocks, and internal power are off; only external power is on).

During the course of normal operation, the software can decide that the chip has been idle for a long enough period that there is no immediate need for the clocks to be active and the chip can be put into a power-down mode such as hibernate. This period of inactivity occurs when there is a USB suspend state (idle on the bus for greater than 3 ms) or if no OTG session is valid. The `SUSPEND_MODE` bit (in `USB_POWER`) and `VBUS1-0` status bits (in `USB_OTG_DEV_CTL`) are used to indicate these states.

Before the system software (driver) pushes processor into the hibernate state, the software has to make sure that the `HIBER` bit (in `USB_PHY_CTL`) is set. Setting this bit activates the non-idle activity detection logic in the PHY. Any non-idle activity on the USB bus is detected by the non-idle activity detection logic in the analog PHY. This logic wakes up the processor and generates a low to high transition on `EXT_WAKE` pin.

To be able to use non-idle activity detection logic as a wakeup source for the processor, enable the USB wakeup source by programming the appropriate bits in the voltage regulator control register (VR\_CTL). After the processor wakes up, USB is listed as the wakeup source in the PLL status (PLL\_STAT) register. The EXT\_WAKE pin can be used by the external power-up sequence chip to power up SDRAM or an other external peripheral. The processor typically goes through these steps (see [Timing Diagram of EXT\\_WAKE Pin](#)) when it comes out of hibernate state.

After the chip comes out of hibernate state, the software has to make sure that the RESTORE bit of the USB\_PHY\_CTL register is set. This setting deactivates the non-idle activity detection logic and ensures proper USB functionality.

**Figure 22-34:** Timing Diagram of EXT\_WAKE Pin

The interrupt will be asserted when either of the following events occur:

- Non-idle signaling occurs during the USB suspend state (including USB reset signaling)
- VBUS falls below the session valid threshold

## Data Transfer

Regardless of whether the USB controller is operating in host or peripheral mode, data is channeled through the endpoint FIFOs to construct packets to be sent or to be received over the USB. The RX FIFOs are used to receive OUT packets when in peripheral mode and IN packets when operating in host mode.

Similarly, the TX FIFOs are used to transmit IN packets when in peripheral mode and OUT packets as a host.

Data may be moved between the FIFOs and memory using either DMA or core accesses. Each endpoint FIFO has its own individually programmable options so that each can be set up separately. Different transfer types must be treated differently by the system. Data transfers of significant size almost certainly require DMA to move the data around; but smaller packet sizes might be handled completely by the processor.

Each data endpoint supports both double and single-buffering modes. In single-buffered operation, FIFOs are unloaded and loaded on a packet-by-packet basis. Double-buffering imposes less burden on the system by allowing two packets to be buffered in a FIFO before it is necessary to use DMA/interrupts to service the FIFO. Double-buffering mode is automatically enabled when a *MaxPktSize* is set for an endpoint that is equal to or less than half the size in bytes of that FIFO.

## Loading/Unloading Packets from Endpoints

Transfers to and from the FIFOs can be 32-bit, 16-bit, or 8-bit as required. When using core accesses the same width must be used for transfers associated with one data packet, so that data is consistently byte, half-word or word aligned. The last transfer may, however, contain fewer bytes than the previous transfers in order to complete an 8-bit or 16-bit transfer.

When using the DMA to access the FIFOs, the only requirement is that the starting DMA address be word aligned, or aligned on a 32-bit boundary. The packet transfer starts with a word transfer, but half-word and/or byte transfers may be added at the end to handle any residue.

## DMA Master Channels

The USB controller provides eight DMA master channels to provide a more efficient transfer of larger amounts of data between the FIFOs and the processor core; and to free up the processor core for other tasks. Each of these channels is configured and controlled using the DMA control registers.

Each DMA controller can operate in one of two DMA modes: 0 or 1. When operating in mode 0, the DMA controller only can be programmed to load or unload one packet, so processor intervention is required for each packet transferred over the USB. This mode can be used with any endpoint, whether it uses control, bulk, isochronous, or interrupt transactions.

When operating in DMA mode 1, the DMA controller can only be programmed to load/unload a complete bulk transfer, which can be many packets. After set up, the DMA controller loads or unloads the packets, interrupting the processor only when the transfer has completed. DMA mode 1 can only be used with endpoints that use bulk transactions. DMA mode 1 is most valuable where large blocks of data are transferred to a bulk endpoint. The USB protocol requires such packets to be split into a series of packets of *MaxPktSize* for the endpoint. Mode 1 can be used to avoid the overhead of having to interrupt the processor after each individual packet; instead the processor is only interrupted after the transfer has completed. In some cases, the block of data transferred comprises a predefined number of these packets

that the controlling software counts through the transfer process. In other cases, the last packet in the series may be less than the maximum packet size and the receiver may use this "short" packet to signal the end of the transfer. If the total size of the transfer is an exact multiple of the maximum packet size, the transmitting software should send a null packet for the receiver to detect.

Each channel can be independently programmed for the selected operating mode.

For bulk OUT transfers using DMA mode 1, the DMA request line is asserted only when there is an edge transition of the state of the `RXPCKTRDY` and a payload of `MaxPacketSize` has been received. If a data packet has been sitting in the FIFO prior to setting `DMAREQMODE1` in `USB_RXCSR`, the DMA request line will not be asserted when the DMA is enabled in the `DMAx_Control` register. This will cause the data not to be read from the RX FIFO, resulting in a DMA "hang". However, since the packet arrived before `DMAREQMODE` and `DMAREQ_ENA` were enabled in `USB_RXCSR`, an RX interrupt will be generated for the corresponding endpoint. Therefore, the software should set the `DMAREQMODE` to Request Mode 0 to unload the pre received packet. The RX interrupt service routine may be similar to the following.

```
If USB_RXCOUNT == MaxPktSize
```

```
    Switch to DMA Mode 0 and unload the packet (in Mode 0, DMA_REQ is always asserted whenever there is data in the FIFO)
```

```
    You should set the DMA_COUNT to MaxPktSize so as to unload only one packet
```

```
    If AUTOCLEAR is set, you do not need to manually clear RXPCKTRDY
```

```
    Switch back to DMA Mode 1 and set the count to
```

```
    (Total_Count - MaxPktSize)
```

```
Else
```

```
    Handle as normal for case of short packet
```

DMA transfers may be 8-bit, 16-bit, or 32-bit. All the transfer associated with one packet (with the exception of the last) must be of the same width, so that the data is consistently byte-aligned or word-aligned. The last transfer may contain fewer bytes than the previous transfers in order to complete an odd-byte or odd-word transfer.

## DMA Bus Cycles

The DMA controller uses incrementing bursts of an unspecified length on the peripheral DMA bus. The controller starts a new burst when it is first granted bus mastership (whether at the start of a USB packet or when regaining the bus after being thrown off part way through a packet) and when the peripheral address starts a new 1K byte block.

When unloading packets from the FIFOs, the DMA controller requests ahead to the USB controller. Although it starts the transfer with two BUSY cycles while it is getting the first word from the FIFO, all subsequent words of the packet are immediately available. No further BUSY cycles are required. The DMA

controller is associated with a two-word buffer, so no data is lost if it loses bus mastership part way through unloading a packet. When bus mastership is regained, it can continue unloading the packet without adding any BUSY cycles.

The DMA start address (written to the `DMAxADDR`) must be word aligned.

Split transactions and retries are supported.

The DMA request lines are individually enabled through the `DMAReqEnab` bit in the appropriate `TxCSR` control register or `RxCSR` control register and operate in two modes, referred to as DMA Request Mode 0 and DMA Request Mode 1. The choice of operating mode is made through the `DMAReqMode` bit in the `TxCSR` for Tx endpoints or `RxCSR` for Rx endpoints).

**NOTE:** When operating in Host mode, if either the `RxStall` bit (bit 5 of `TxCSRL` register) or the Error bit (bit 2 of `TxCSRL` register) becomes set following three failed attempts to transmit a packet, the DMA request line will be disabled until the `RxStall/Error` bit(s) have been cleared.

The mode selected also affects the generation of Endpoint interrupts (if enabled). In DMA Request Mode 0, no interrupt is generated when packets are received but the appropriate Endpoint interrupt is generated to prompt the loading of all packets. In DMA Request Mode 1, the Endpoint interrupt is suppressed except following the receipt of a short packet (one of less than `RxMaxP` bytes).

**Table 22-7:** Endpoint Interrupt associated with `RxPktRdy` being set

| <code>DMAReqEnab</code> | <code>DMAReqMode</code> | EP Interrupt Generated? |
|-------------------------|-------------------------|-------------------------|
| 0                       | X                       | YES                     |
| 1                       | 0                       | NO                      |
| 1                       | 1                       | Only is short packet    |

**Table 22-8:** Endpoint Interrupt associated with `RxPktRdy` being set

| <code>DMAReqEnab</code> | <code>DMAReqMode</code> | EP Interrupt Generated? |
|-------------------------|-------------------------|-------------------------|
| 0                       | X                       | YES                     |
| 1                       | 0                       | YES                     |
| 1                       | 1                       | NO                      |

**NOTE:** `Tx/RxMaxP` must be set to an even number of bytes for proper interrupt generation in DMA Mode 1.

DMA transfers may be 8-bit, 16-bit, or 32-bit as required. However, all the transfers associated with one packet (with the exception of the last) must be of the same width so that the data is consistently byte-,

word- or double-word-aligned. The last transfer may contain fewer bytes than the previous transfers in order to complete an odd-byte or odd-word transfer.

**NOTE:** DMA Requests should be disabled before the DMA Request Mode is changed. In particular, the DMAReqMode bit in the TxCSRH register should not be set to zero either before or in the same cycle as the corresponding DMAReqEnab bit is cleared to zero.

## Transferring Packets Using DMA

Use of the DMA master channels to access the USB controller FIFOs requires that both the appropriate channel and the endpoint be programmed appropriately. Many variations are possible. The following sections detail the standard setups used for the basic actions of transferring individual packets and multiple packets.

### Individual Packet: RX Endpoint

The transfer of individual packets is normally carried out using DMA mode 0. The USB controller RX endpoint is programmed as follows:

1. The relevant EPx\_RX\_E bit in the USB\_INTRRXE register is set to 1.
2. The DMA\_ENA bit of the appropriate USB\_RXCSR register is set to 0. (There is no need to set the USB controller to support DMA for this operation.)
3. When a packet is received by the USB controller, it generates the appropriate endpoint interrupt (using USB\_INTRRX). The processor should then program the appropriate DMA master channel as follows:
  - DMAxADDR: memory address to store packet
  - USB\_DMAxCOUNT: size of packet (determined by reading the USB controller USB\_RXCOUNT register)
  - USB\_DMAxCONTROL: INT\_ENA = 1, DMA\_ENA = 1, DIRECTION = 0, DMAREQMODE\_R = 0

The DMA controller then requests bus mastership and transfers the packet to memory. It interrupts the processor when it has completed the transfer. The processor should then clear the RXPkTRDY bit in the USB\_RXCSR register.

### Individual Packet: TX Endpoint

Again using DMA mode 0, a USB controller TX endpoint is programmed as follows.

1. The relevant EPx\_TX\_E bit in the USB\_INTRTXE register is set to 1.
2. The DMA\_ENA bit of the appropriate USB\_TxCSR register is set to 0. (There is no need to set the USB controller to support DMA for this operation.)

3. When the FIFO can accommodate data, the USB controller interrupts the processor with the appropriate TX endpoint interrupt. The processor should then program the DMA channel as follows:
  - `DMAxADDR`: memory address of packet to send
  - `USB_DMAxCOUNT`: size of packet to be sent
  - `USB_DMAxCONTROL`: `INT_ENA = 1`, `DMA_ENA = 1`, `DIRECTION = 1`, `DMAREQMODE_T = 0`

The DMA controller then requests bus mastership and transfers the packet to the USB controller FIFO. When it has completed the transfer, it generates a DMA interrupt. The processor should then set the `TXPK-TRDY` bit in the `USB_TXCSR` register.

## Multiple Packets: RX Endpoint

Multiple packets normally are transferred using DMA mode 1. The DMA controller is programmed using the DMA registers:

- `DMAxADDR`: memory address of the buffer in which to store transfer
- `USB_DMAxCOUNT`: maximum size of data buffer
- `USB_DMAxCONTROL`: `INT_ENA = 1`, `DMA_ENA = 1`, `DIRECTION = 0`, `DMAREQMODE_R = 1`

The USB controller RX endpoint should now be programmed as follows:

1. The relevant `EPx_RX_E` bit in the `USB_INTRRXE` register is set to 1.
2. The `AUTOCLEAR_R`, `DMAREQ_ENA_R` and `DMAREQMODE_R` bits of the appropriate `USB_RXCSR` register is set to 1. In host mode, the `AUTOREQ_RH` and `DMAREQMODE_RH` bits should also be set to 1.

As each packet is received by the USB controller, the DMA master channel requests bus mastership and transfers the packet to memory. With `AUTOCLEAR_R` set, the USB controller automatically clears its `RXPK-TRDY` bit. This process continues automatically until the USB controller receives a short packet (one of less than the maximum packet size for the endpoint) signifying the end of the transfer. This short packet is not transferred by the DMA controller: instead the USB controller interrupts the processor by generating the appropriate endpoint interrupt. The processor can then read the `USB_RXCOUNT` register to see the size of the short packet and either unload it manually or reprogram the DMA controller in mode 0 to unload the packet.

The `DMAxADDR` register is incremented as the packets are unloaded, so the processor can determine the size of the transfer by comparing the current value of `DMAxADDR` with the start address of the memory buffer.

If the size of the transfer exceeds the data buffer size, the DMA controller stops unloading the FIFO and interrupts the processor.

## Multiple Packets: TX Endpoints

Using DMA mode 1 for a TX endpoint, the DMA controller is programmed as follows:

- **DMAxADDR:** memory address of data block to send
- **USB\_DMAxCOUNT:** size of data block
- **USB\_DMAxCONTROL:** `INT_ENA = 1`, `DMA_ENA = 1`, `DIRECTION = 1`, `DMAREQMODE_T = 1`

The USB controller TX endpoint is programmed as follows:

1. The relevant `EPx_TX_E` bit in the `USB_INTRTXE` register is set to 1.
2. The `AUTOSET_T` and `DMA_ENA` bits of the appropriate `USB_EP_NIx_TXCSR` register is set to 1.

When the FIFO in the USB controller becomes available, the DMA controller requests bus mastership and transfers a packet to the FIFO. With `AUTOSET_T` set, the USB controller automatically sets the `TXPKTRDY` bit. This process continues until the entire data block is transferred to the USB controller. The DMA controller then interrupts the processor by taking `DMAx_INT` low. If the last packet to be loaded was less than the maximum packet size for the endpoint, the `TXPKTRDY` bit is not set for this packet; the processor should respond to the DMA interrupt by setting the `TXPKTRDY` bit to allow the last short packet to be sent. If the last packet to be loaded was of the maximum packet size, then the action to take depends on whether the transfer is under the control of an application such as the mass storage software on Windows system that keeps count of the individual packets sent. If the transfer is not under such control, the processor should still respond to the DMA interrupt by setting the `TXPKTRDY` bit. This has the effect of sending a null packet for the receiving software to interpret as indicating the end of the transfer.

## USB Register Descriptions

Universal Serial Bus Controller (USB) contains the following registers.

**Table 22-9:** USB Module Registers

| Name        | Description                        |
|-------------|------------------------------------|
| USB_FADDR   | Function Address Register          |
| USB_POWER   | Power and Device Control Register  |
| USB_INTRTX  | Transmit Interrupt Register        |
| USB_INTRRX  | Receive Interrupt Register         |
| USB_INTRTXE | Transmit Interrupt Enable Register |
| USB_INTRRXE | Receive Interrupt Enable Register  |

**Table 22-9:** USB Module Registers (Continued)

| Name               | Description                            |
|--------------------|----------------------------------------|
| USB_IRQ            | Common Interrupts Register             |
| USB_IEN            | Common Interrupts Enable Register      |
| USB_FRAME          | Frame Number Register                  |
| USB_INDEX          | Index Register                         |
| USB_TESTMODE       | Testmode Register                      |
| USB_FIFOBn         | FIFO Byte (8-Bit) Register             |
| USB_FIFOHn         | FIFO Half-Word (16-Bit) Register       |
| USB_FIFOn          | FIFO Word (32-Bit) Register            |
| USB_DEV_CTL        | Device Control Register                |
| USB_TXFIFOSZ       | Transmit FIFO Size Register            |
| USB_RXFIFOSZ       | Receive FIFO Size Register             |
| USB_TXFIFOADDR     | Transmit FIFO Address Register         |
| USB_RXFIFOADDR     | Receive FIFO Address Register          |
| USB_EPINFO         | Endpoint Information Register          |
| USB_RAMINFO        | RAM Information Register               |
| USB_LINKINFO       | Link Information Register              |
| USB_VPLEN          | VBUS Pulse Length Register             |
| USB_HS_EOF1        | High-Speed EOF 1 Register              |
| USB_FS_EOF1        | Full-Speed EOF 1 Register              |
| USB_LS_EOF1        | Low-Speed EOF 1 Register               |
| USB_SOFT_RST       | Software Reset Register                |
| USB_MPN_TXFUNCADDR | MPn Transmit Function Address Register |

**Table 22-9:** USB Module Registers (Continued)

| Name               | Description                                                 |
|--------------------|-------------------------------------------------------------|
| USB_MPn_TXHUBADDR  | MPn Transmit Hub Address Register                           |
| USB_MPn_TXHUBPORT  | MPn Transmit Hub Port Register                              |
| USB_MPn_RXFUNCADDR | MPn Receive Function Address Register                       |
| USB_MPn_RXHUBADDR  | MPn Receive Hub Address Register                            |
| USB_MPn_RXHUBPORT  | MPn Receive Hub Port Register                               |
| USB_EPn_TXMAXP     | EPn Transmit Maximum Packet Length Register                 |
| USB_EP0_CSRn_H     | EP0 Configuration and Status (Host) Register                |
| USB_EP0_CSRn_P     | EP0 Configuration and Status (Peripheral) Register          |
| USB_EPn_TXCSR_H    | EPn Transmit Configuration and Status (Host) Register       |
| USB_EPn_TXCSR_P    | EPn Transmit Configuration and Status (Peripheral) Register |
| USB_EPn_RXMAXP     | EPn Receive Maximum Packet Length Register                  |
| USB_EPn_RXCSR_H    | EPn Receive Configuration and Status (Host) Register        |
| USB_EPn_RXCSR_P    | EPn Receive Configuration and Status (Peripheral) Register  |
| USB_EP0_CNTn       | EP0 Number of Received Bytes Register                       |
| USB_EPn_RXCNT      | EPn Number of Bytes Received Register                       |
| USB_EPn_TXTYPE     | EPn Transmit Type Register                                  |
| USB_EP0_TYPERn     | EP0 Connection Type Register                                |
| USB_EP0_NAKLIMITn  | EP0 NAK Limit Register                                      |
| USB_EPn_TXINTERVAL | EPn Transmit Polling Interval Register                      |
| USB_EPn_RXTYPE     | EPn Receive Type Register                                   |
| USB_EPn_RXINTERVAL | EPn Receive Polling Interval Register                       |
| USB_EP0_CFGDATAn   | EP0 Configuration Information Register                      |

**Table 22-9:** USB Module Registers (Continued)

| Name                       | Description                                   |
|----------------------------|-----------------------------------------------|

| USB_RQPKTCNT <sub>n</sub>  | EP <sub>n</sub> Request Packet Count Register |
| USB_CT_UCH                 | Chirp Timeout Register                        |
| USB_CT_HHSRTN              | Host High Speed Return to Normal Register     |
| USB_CT_HSBT                | High Speed Timeout Register                   |
| USB_LPM_ATTR               | LPM Attribute Register                        |
| USB_LPM_CTL                | LPM Control Register                          |
| USB_LPM_IEN                | LPM Interrupt Enable Register                 |
| USB_LPM_IRQ                | LPM Interrupt Status Register                 |
| USB_LPM_FADDR              | LPM Function Address Register                 |
| USB_VBUS_CTL               | VBUS Control Register                         |
| USB_BAT_CHG                | Battery Charging Control Register             |
| USB_PHY_CTL                | PHY Control Register                          |
| USB_PLL_OSC                | PLL and Oscillator Control Register           |

## Function Address Register

The USB\_FADDR register contains the device address used in peripheral mode. The processor writes this register with the address received through a SET\_ADDRESS command from the host.

USB\_FADDR: Function Address Register - R/W

Reset = 0x00

Figure 22-35: USB\_FADDR Register Diagram

Table 22-10: USB\_FADDR Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                            |
|---------|----------|--------------------------------------------------------------------------------------------------------------------|
| 6:0     | VALUE    | Function Address Value.<br>The USB_FADDR.VALUE bits contain the address of the peripheral part of the transaction. |

Power and Device Control Register

The USB\_POWER register controls suspend and resume signaling and controls some operational aspects of the USB controller.

USB\_POWER: Power and Device Control Register - R/W

Reset = 0x20

Figure 22-36: USB\_POWER Register Diagram

**Table 22-11:** USB\_POWER Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7       | ISOUPDT  | ISO Update Enable.<br>The <code>USB_POWER.ISOUPDT</code> bit directs the USB controller to wait for an SOF token from the time <code>TXPKTRDY</code> is set before sending the packet. If an IN token is received before an SOF token, the USB controller sends a zero length data packet. This <code>USB_POWER.ISOUPDT</code> bit only affects endpoints performing isochronous transfers. This bit only is valid in peripheral mode ( <code>USB_DEV_CTL.HOSTMODE = 0</code> ).                                                                                                                                             |
|         |          | 0      Disable ISO Update                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|         |          | 1      Enable ISO Update                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 6       | SOFTCONN | Soft Connect/Disconnect Enable.<br>In peripheral mode, the D+/- lines default to disconnected. Setting this bit will enable the D+/- termination resistors. This bit is automatically set when the <code>DevCtl.Session</code> bit is written with '1'. The <code>USB_POWER.SOFTCONN</code> bit enables USB controller soft connect/disconnect, enabling the termination resistors for <code>USB_DP</code> (Data +) and <code>USB_DM</code> (Data -) pins. When disabled, these pins are three-stated. Note that <code>USB_POWER.SOFTCONN</code> only is valid in peripheral mode ( <code>USB_DEV_CTL.HOSTMODE = 0</code> ). |
|         |          | 0      Disable Soft Connect/Disconnect                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|         |          | 1      Enable Soft Connect/Disconnect                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 5       | HSEN     | High Speed Mode Enable.<br>The <code>USB_POWER.HSEN</code> bit enables USB controller negotiation for high speed when the device is reset by the hub/host. If disabled, the USB controller only operates in full-speed mode.                                                                                                                                                                                                                                                                                                                                                                                                 |
|         |          | 0      Disable Negotiation for HS Mode                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Table 22-11:** USB\_POWER Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4       | HSMODE   | High Speed Mode.<br>The USB_POWER.HSMODE bit indicates whether or not the USB controller successfully negotiated high-speed mode during a USB controller reset. In peripheral mode (USB_DEV_CTL.HOSTMODE = 0), this bit has valid data when the USB controller completes reset. In host mode (USB_DEV_CTL.HOSTMODE = 1), this bit has valid data when the USB_IRQ.RSTBABBLE bit is cleared, remaining valid for the duration of the session.                                                  |
|         |          | 0 Full Speed Mode (HS fail during reset)                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|         |          | 1 High Speed Mode (HS success during reset)                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 3       | RESET    | Reset USB.<br>The USB_POWER.RESET bit indicates (in both host and peripheral modes) that the USB controller has detected that reset signaling is present on the bus. In peripheral mode (USB_DEV_CTL.HOSTMODE = 0), this bit is read only, but in host mode (USB_DEV_CTL.HOSTMODE = 1), this bit is read/write, permitting the processor core to set the bit and initiate a USB controller reset.                                                                                             |
|         |          | 0 No Reset                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|         |          | 1 Reset USB                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 2       | RESUME   | Resume Mode.<br>The USB_POWER.RESUME bit directs the USB controller to generate resume signaling when the function is in suspend mode (USB_POWER.SUSPEND = 1). The processor core should clear this bit after 10 ms (a maximum of 15 ms) to end resume signaling. When the USB controller is in host mode (USB_DEV_CTL.HOSTMODE = 1), the USB controller automatically sets the USB_POWER.RESUME bit when resume signaling from the target is detected while the USB controller is suspended. |
|         |          | 0 Disable Resume Signaling                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|         |          | 1 Enable Resume Signaling                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 22-11:** USB\_POWER Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1       | SUSPEND  | Suspend Mode.<br>When the USB controller is in host mode (USB_DEV_CTL.HOSTMODE = 1), the USB_POWER.SUSPEND bit enables suspend mode. When the USB controller is in peripheral mode (USB_DEV_CTL.HOSTMODE = 0), the USB controller sets the USB_POWER.SUSPEND bit on entry to suspend mode and clears the bit when the processor reads the USB_IRQ register. Note that the USB controller automatically clears this bit if the USB_POWER.RESUME bit is set. |
|         |          | 0      Disable Suspend Mode (Host)                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Common Interrupts Register

The `USB_IRQ` register indicates which interrupts are currently active for USB controller system sources. Note that the USB controller automatically clears this register when it is read.

USB\_IRQ: Common Interrupts Register - R/NW

Reset = 0x00

Table 22-16: USB\_IRQ Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                  |                   |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| 7       | VBUSERR  | VBUS Threshold Indicator.<br>The USB_IRQ.VBUSERR bit indicates whether the USB controller has detected that the VBUS is below the VBUS valid threshold. This bit is valid only when the USB controller is an A device. Note that the USB_IRQ.VBUSERR bit and the USB_VBUS_CTL.DRVINT bit share an interrupt source line. |                   |
|         |          | 0                                                                                                                                                                                                                                                                                                                        | No Interrupt      |
|         |          | 1                                                                                                                                                                                                                                                                                                                        | Interrupt Pending |
| 6       | SESSREQ  | Session Request Indicator.<br>The USB_IRQ.SESSREQ bit indicates whether the USB controller has detected a session request signal. This bit is valid only when the USB controller is an A device.                                                                                                                         |                   |
|         |          | 0                                                                                                                                                                                                                                                                                                                        | No Interrupt      |
|         |          | 1                                                                                                                                                                                                                                                                                                                        | Interrupt Pending |

**Table 22-16:** USB\_IRQ Register Fields (Continued)

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                                                                                                     |
|---------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5       | DISCON    | Disconnect Indicator.<br>The <code>USB_IRQ.DISCON</code> bit indicates whether the USB controller has detected a device disconnect (host mode) or has detected a session end (peripheral mode).                                                                                                                                             |
|         |           | 0 No Interrupt                                                                                                                                                                                                                                                                                                                              |
|         |           | 1 Interrupt Pending                                                                                                                                                                                                                                                                                                                         |
| 4       | CON       | Connection Indicator.<br>The <code>USB_IRQ.CON</code> bit indicates whether the USB controller has detected a device connection. This bit is valid only in host mode.                                                                                                                                                                       |
|         |           | 0 No Interrupt                                                                                                                                                                                                                                                                                                                              |
|         |           | 1 Interrupt Pending                                                                                                                                                                                                                                                                                                                         |
| 3       | SOF       | Start-of-frame Indicator.<br>The <code>USB_IRQ.SOF</code> bit indicates whether the USB controller has detected a start of frame.                                                                                                                                                                                                           |
|         |           | 0 No Interrupt                                                                                                                                                                                                                                                                                                                              |
|         |           | 1 Interrupt Pending                                                                                                                                                                                                                                                                                                                         |
| 2       | RSTBABBLE | Reset/Babble Indicator.<br>The <code>USB_IRQ.RSTBABBLE</code> bit indicates whether the USB controller has detected reset signalling on the bus. In host mode, the USB controller also indicates when the USB controller detects babble. Note that the <code>USB_IRQ.RSTBABBLE</code> bit is only active after the first SOF has been sent. |
|         |           | 0 No Interrupt                                                                                                                                                                                                                                                                                                                              |
|         |           | 1 Interrupt Pending                                                                                                                                                                                                                                                                                                                         |

**Table 22-16:** USB\_IRQ Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1       | RESUME   | Resume Indicator.<br>The <code>USB_IRQ.RESUME</code> bit indicates whether the USB controller has detected resume signaling on the bus while the USB controller is in suspend mode.    |
|         |          | 0 No Interrupt                                                                                                                                                                         |
|         |          | 1 Interrupt Pending                                                                                                                                                                    |
| 0       | SUSPEND  | Suspend Indicator.<br>The <code>USB_IRQ.SUSPEND</code> bit indicates whether the USB controller has detected suspend signalling on the bus. This bit is valid only in peripheral mode. |
|         |          | 0 No Interrupt                                                                                                                                                                         |
|         |          | 1 Interrupt Pending                                                                                                                                                                    |

## Common Interrupts Enable Register

The `USB_IEN` register enables interrupts for USB controller system sources. Enabling an interrupt in this register directs the USB controller to generate an interrupt if the corresponding interrupt pending bit in the `USB_IRQ` register is set.

**USB\_IEN: Common Interrupts Enable Register - R/W**

Reset = 0x00

|---------|----------|---------------------------------------------------------------------------------------------------------------------------------|
| 1       | RESUME   | Resume Indicator Interrupt Enable.<br>The <code>USB_IEN.RESUME</code> bit enables the <code>USB_IRQ.RESUME</code> interrupt.    |
|         |          | 0                      Disable Interrupt                                                                                        |
|         |          | 1                      Enable Interrupt                                                                                         |
| 0       | SUSPEND  | Suspend Indicator Interrupt Enable.<br>The <code>USB_IEN.SUSPEND</code> bit enables the <code>USB_IRQ.SUSPEND</code> interrupt. |
|         |          | 0                      Disable Interrupt                                                                                        |
|         |          | 1                      Enable Interrupt                                                                                         |

## Frame Number Register

The `USB_FRAME` register contains the frame number of the last received frame. The data in this register has bit 10 as the MSB and bit 0 as the LSB.

**USB\_FRAME: Frame Number Register - R/NW**

Reset = 0x0000

**Figure 22-43:** USB\_FRAME Register Diagram

**Table 22-18:** USB\_FRAME Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                               |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10:0    | VALUE    | Frame Number Value.<br>The <code>USB_FRAME.VALUE</code> bits contains the frame number of the last received frame. The data in this field has bit 10 as the MSB and bit 0 as the LSB. |

## Index Register

The `USB_INDEX` register contains an index value for mirrored addressing of USB controller endpoint control and status registers.

There is one set of registers, but they are mirrored at two address locations if the endpoint is selected by the `USB_INDEX` register. An endpoint's register set only appears in the indexed location if the `USB_INDEX` register is written with that endpoint number. You can read/write an endpoint's register in either the directly mapped location which is always visible, or in the indexed location which is only visible if the `USB_INDEX` register is written with the endpoint number. The `USB_INDEX` register and indexed address locations only affect address decoding. For example, loading a 0 into the `USB_INDEX` register selects endpoint 0 access.

The `USB_INDEX` register can be used for indexed access of the directly mapped control/status registers from USB controller address offset 0x100-0x1FF. The endpoint `USB_TXFIFOSZ`, `USB_RXFIFOSZ`, `USB_TXFIFOADDR`, and `USB_RXFIFOADDR` registers always use the `USB_INDEX` register, there is no direct mapping for these endpoint specific registers. The multipoint `USB_MPn_TXFUNCADDR`, `USB_MPn_TXHUBADDR`, `USB_MPn_TXHUBPORT`, `USB_MPn_RXFUNCADDR`, `USB_MPn_RXHUBADDR`, and `USB_MPn_RXHUBPORT` register only have direct mapping, no indexed mapping.

Before accessing an endpoint's control/status registers using the indexed range, write the endpoint number to the `USB_INDEX` register to ensure that the correct control/status registers appear in the indexed range of the memory map.

Figure 22-44: `USB_INDEX` Register Diagram

Table 22-19: `USB_INDEX` Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                           |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3:0     | EP       | Endpoint Index.<br>The <code>USB_INDEX</code> . EP bits selects mirrored access for an endpoint's indexed control and status registers. Valid values for this bit field are 0-11. |

## Testmode Register

The `USB_TESTMODE` register places the USB controller into test mode state and can also put the USB controller into one of the test modes for high-speed operation. For more information about these modes, see the USB 2.0 specification.

Note that the `USB_TESTMODE` register is not used in normal operation. Only one of the test mode (bits 0-6) selection bits may be set at a time.

**USB\_TESTMODE: Testmode Register - R/W**

Reset = 0x00

**Figure 22-45:** USB\_TESTMODE Register Diagram

**Table 22-20:** USB\_TESTMODE Register Fields

| Bit No. | Bit Name   | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6       | FIFOACCESS | FIFO Access.<br>The <code>USB_TESTMODE</code> bit directs the USB controller to transfer the packet in the endpoint 0 Tx FIFO to the endpoint 0 Rx FIFO. The bit is cleared automatically.                                                                                                                                                                                                                                                               |
| 3       | TESTPACKET | Test_Packet Mode.<br>The <code>USB_TESTMODE.TESTPACKET</code> bit selects Test_Packet test mode, which applies only when the USB controller in high speed mode. In this mode, the USB controller repetitively transmits on the bus a 53-byte test packet, whose form is defined in the USB 2.0 Specification, Section 7.1.20. Note that the test packet has a fixed format and must be loaded into the endpoint 0 FIFO before this test mode is entered. |
| 2       | TESTK      | Test_K Mode.<br>The <code>USB_TESTMODE.TESTK</code> bit selects Test_K test mode. In this mode, the USB controller transmits a continuous K on the bus.                                                                                                                                                                                                                                                                                                  |

Table 22-20: USB\_TESTMODE Register Fields (Continued)

| Bit No. | Bit Name   | Description/Enumeration                                                                                                                                                                                                                                     |
|---------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1       | TESTJ      | Test_J Mode.<br>The USB_TESTMODE.TESTJ bit selects Test_J test mode. In this mode, the USB controller transmits a continuous J on the bus.                                                                                                                  |
| 0       | TESTSE0NAK | Test SE0 NAK.<br>The USB_TESTMODE.TESTSE0NAK bit selects Test_SE0_NAK test mode, which applies only when the USB controller in high speed mode. In this mode, the USB controller remains in high-speed mode, but responds to any valid IN token with a NAK. |

FIFO Byte (8-Bit) Register

Writes to the USB\_FIFOBn register go to the endpoint Tx FIFO and reads from the USB\_FIFOBn register come from the endpoint Rx FIFO. The USB\_FIFOBn, USB\_FIFOHn, and USB\_FIFOn registers are one and the same. These registers exist at the same address. Typically, programs should load and unload the FIFO using word (USB\_FIFOn register) writes and reads, which are more efficient. Only if the USB packet is a non-word (4-byte) size should the program use a half-word (USB\_FIFOHn register) or byte (USB\_FIFOBn register) read or write at the end when loading or unloading the FIFO.

Note that (for correct USB controller operation) programs should not mix byte, half-word, or word accesses, except for the last few bytes if the size of the packet is odd (not a multiple of the size they were using).

Table 22-21: USB\_FIFOBn Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                              |
|---------|----------|------------------------------------------------------------------------------------------------------|
| 7:0     | FIFO     | FIFO Byte Data.<br>The USB_FIFOBn.FIFO bits provide byte access to the USB Tx and Rx endpoint FIFOs. |

## FIFO Half-Word (16-Bit) Register

Writes to the USB\_FIFOHn register go to the endpoint Tx FIFO and reads from the USB\_FIFOHn register come from the endpoint Rx FIFO. The USB\_FIFOBn, USB\_FIFOHn, and USB\_FIFOn registers are one and the same. These registers exist at the same address. Typically, programs should load and unload the FIFO using word (USB\_FIFOn register) writes and reads, which are more efficient. Only if the USB packet is a non-word (4-byte) size should the program use a half-word (USB\_FIFOHn register) or byte (USB\_FIFOBn register) read or write at the end when loading or unloading the FIFO.

Note that (for correct USB controller operation) programs should not mix byte, half-word, or word accesses, except for the last few bytes if the size of the packet is odd (not a multiple of the size they were using).

| Bit No. | Bit Name | Description/Enumeration                                                                                        |
|---------|----------|----------------------------------------------------------------------------------------------------------------|
| 15:0    | FIFO     | FIFO Half-Word Data.<br>The USB_FIFOHn.FIFO bits provide half-word access to the USB Tx and Rx endpoint FIFOs. |

## FIFO Word (32-Bit) Register

Writes to the USB\_FIFOn register go to the endpoint Tx FIFO and reads from the USB\_FIFOn register come from the endpoint Rx FIFO. The USB\_FIFOBn, USB\_FIFOHn, and USB\_FIFOn registers are one and the same. These registers exist at the same address. Typically, programs should load and unload the FIFO using word (USB\_FIFOn register) writes and reads, which are more efficient. Only if the USB packet is a non-word (4-byte) size should the program use a half-word (USB\_FIFOHn register) or byte (USB\_FIFOBn register) read or write at the end when loading or unloading the FIFO.

Note that (for correct USB controller operation) programs should not mix byte, half-word, or word accesses, except for the last few bytes if the size of the packet is odd (not a multiple of the size they were using).

USB\_FIFOn: FIFO Word (32-Bit) Register - R/W

Reset = 0x0000 0000

Table 22-23: USB\_FIFOn Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                              |
|---------|----------|------------------------------------------------------------------------------------------------------|
| 31:0    | VALUE    | FIFO Word Data.<br>The USB_FIFOn.VALUE bits provide word access to the USB Tx and Rx endpoint FIFOs. |

Device Control Register

The USB\_DEV\_CTL register selects whether the USB controller is operating in peripheral mode or in host mode and is used for controlling and monitoring the VBUS line.

USB\_DEV\_CTL: Device Control Register - R/W

Reset = 0x00

|         |          | 1 Place Request                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 0       | SESSION  | Session Indicator.<br>When operating as an A device, the <code>USB_DEV_CTL.SESSION</code> is set or cleared by the processor core to start or end a session. When operating as a B device, the <code>USB_DEV_CTL.SESSION</code> bit is set or cleared by the USB controller when a session starts or ends. This bit is also set by the processor core to initiate the session request protocol. When the USB controller is in Suspend mode, the bit may be cleared by the processor core to perform a software disconnect. |

## Transmit FIFO Size Register

The `USB_TXFIFOSZ` register defines the maximum amount of data that can be transferred through the selected transmit endpoint in a single frame. When setting this value, you must consider the constraints placed by the USB specification on packet sizes for bulk, interrupt and isochronous transactions in full-speed operations. This register provides indexed access to the FIFO (packet) size selection for each Tx endpoint (except endpoint 0).

USB\_TXFIFOSZ: Transmit FIFO Size Register - R/W

Reset = 0x00

## Receive FIFO Size Register

The `USB_RXFIFOSZ` register defines the maximum amount of data that can be transferred through the selected receive endpoint in a single frame. When setting this value, you must consider the constraints placed by the USB specification on packet sizes for bulk, interrupt and isochronous transactions in full-speed operations. This register provides indexed access to the FIFO (packet) size selection for each Rx endpoint (except endpoint 0).

Note that a value greater than the maximum allowed of 1023 for full-speed USB controller operation produces unpredictable results.

Also note that the value written to this register should match the programmed maximum individual packet size (MaxPktSize) of the standard endpoint descriptor for the associated endpoint (see Universal Serial Bus Specification Revision 2.0, Chapter 9). A mismatch could cause unexpected results. The total amount of data represented by the value written to this register must not exceed the Rx FIFO size, and should not exceed half the FIFO size if double-buffering is required.

USB\_RXFIFOSZ: Receive FIFO Size Register - R/W

## Transmit FIFO Address Register

The `USB_TXFIFOADDR` sets the start address for the selected Tx FIFO for endpoints 1-11. There is one transmit FIFO address register for each endpoint, except endpoint 0. The `USB_TXFIFOADDR` register is indexed and selected by the `USB_INDEX` register. Note that the endpoint 0 FIFO has a fixed 64-byte size and is always located at address 0.

USB\_TXFIFOADDR: Transmit FIFO Address Register - R/W

Reset = 0x0000

Figure 22-52: USB\_TXFIFOADDR Register Diagram

Table 22-27: USB\_TXFIFOADDR Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                      |

|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | VALUE    | VBUS Pulse Length Value.<br>The USB_VPLEN.VALUE bits sets the duration of the VBUS pulsing charge in units of 546.1us. The default setting corresponds to 32.77ms. Note that VBUS pulsing was removed in the OTG specification v2.0, section 5.1.4. |

## High-Speed EOF 1 Register

The `USB_HS_EOF1` register defines the minimum time gap allowed between the start of the last transaction and the end of frame for high-speed transactions.

USB\_HS\_EOF1: High-Speed EOF 1 Register - R/W

Reset = 0x80

Figure 22-58: USB\_HS\_EOF1 Register Diagram

Table 22-33: USB\_HS\_EOF1 Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                           |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | VALUE    | High-Speed EOF 1 Value.<br>The <code>USB_HS_EOF1.VALUE</code> sets the time before end of frame to stop beginning new transactions (in units of 133.3ns) for high-speed transactions. The default setting corresponds to 17.07us. |

## Full-Speed EOF 1 Register

The `USB_FS_EOF1` register defines the minimum time gap allowed between the start of the last transaction and the end of frame for full-speed transactions.

USB\_FS\_EOF1: Full-Speed EOF 1 Register - R/W

Reset = 0x77

Figure 22-59: USB\_FS\_EOF1 Register Diagram

Table 22-34: USB\_FS\_EOF1 Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                               |

Low-Speed EOF 1 Register

The `USB_LS_EOF1` register defines the minimum time gap allowed between the start of the last transaction and the end of frame for low-speed transactions.

USB\_LS\_EOF1: Low-Speed EOF 1 Register - R/W  
  
Reset = 0x72

Figure 22-60: USB\_LS\_EOF1 Register Diagram

Table 22-35: USB\_LS\_EOF1 Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                             |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | VALUE    | Low-Speed EOF 1 Value.<br>The <code>USB_LS_EOF1.VALUE</code> bits set the time before end of frame to stop beginning new transactions (in units of 1.067us) for low-speed transactions. The default setting corresponds to 121.6us. |

Software Reset Register

The `USB_SOFT_RST` register provides reset controls for the USB controller CLK domain and XCLK domain. The USB controller PHY operates in the controller's XCLK domain, and the USB controller interface to the processor core operates in the controller's CLK domain. Note that for correct operation, both of the reset control bits (`USB_SOFT_RST.RST` and `USB_SOFT_RST.RSTX`) should always be asserted simultaneously.

USB\_SOFT\_RST: Software Reset Register - R/W

Figure 22-61: USB\_SOFT\_RST Register Diagram

Table 22-36: USB\_SOFT\_RST Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                        |                       |

| Bit No. | Bit Name | Description/Enumeration                                                                                                  |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------|
| 6:0     | VALUE    | Tx Function Address Value.<br>The USB_MPN_TXFUNCADDR.VALUE bits hold the address of the target device for this endpoint. |

MPn Transmit Hub Address Register

The USB\_MPN\_TXHUBADDR register specifies the hub address of the endpoint in host mode. This register is not used in device mode. Note that this register only needs to be programmed when a full-speed or low-speed device is connected to a high-speed hub, which carries out the necessary transaction translation. Also note that EP0 only uses the USB\_MPN\_TXHUBADDR register. (The USB\_MPN\_RXHUBADDR register does not exist for EP0.)

USB\_MPN\_TXHUBADDR: MPn Transmit Hub Address Register - R/W

Reset = 0x00

Figure 22-63: USB\_MPN\_TXHUBADDR Register Diagram

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                 |
|---------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 7       | MULTTRANS | Multiple Transaction Translators.<br>The USB_MPn_TXHUBADDR.MULTTRANS bit should be set if the hub has multiple transaction translators. |
|         |           | 0                      Single Transaction Translator                                                                                    |
|         |           | 1                      Multiple Transaction Translators                                                                                 |
| 6:0     | ADDR      | Hub Address Value.<br>The USB_MPn_TXHUBADDR.ADDR bits hold the address of the hub to which this device is connected.                    |

MPn Transmit Hub Port Register

The USB\_MPn\_TXHUBPORT register specifies the hub port for full-speed and low-speed endpoints in host mode. This register is not used in device mode. The USB\_MPn\_TXHUBPORT register lets the USB controller support SPLIT transactions. EP0 only uses the USB\_MPn\_TXHUBPORT register. (The USB\_MPn\_RXHUBPORT register does not exist for EP0.)

USB\_MPn\_TXHUBPORT: MPn Transmit Hub Port Register - R/W

Reset = 0x00

|---------|----------|---------------------------------------------------------------------------------------------------------------------|
| 6:0     | VALUE    | Hub Port Value.<br>The USB_MPn_RXHUBPORT.VALUE bits hold the hub port value of the target device for this endpoint. |

## EPn Transmit Maximum Packet Length Register

The USB\_EPn\_TXMAXP register defines the maximum amount of data that can be transferred through the selected transmit endpoint in a single frame. When setting this value, you must consider the constraints

placed by the USB specification on packet sizes for bulk, interrupt and isochronous transactions in full-speed operations. The `USB_EPn_TXMAXP` register provides indexed access to the maximum packet length register for each Tx endpoint, except endpoint 0.

**USB\_EPn\_TXMAXP: EPn Transmit Maximum Packet Length Register - R/W**

Reset = 0x0000

**Figure 22-68:** USB\_EPn\_TXMAXP Register Diagram

**Table 22-43:** USB\_EPn\_TXMAXP Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 12:11   | MULTM1   | Multi-Packets per Micro-frame.<br>The <code>USB_EPn_TXMAXP.MULTM1</code> bits select the number of high-speed high-bandwidth isochronous or interrupt packets that may be transferred in a microframe. The valid number of packets per microframe is 1-3 which corresponds to settings 0-2. If this field is not zero, the USB controller splits the FIFO data into multiple packets less than or equal to the maximum payload size.                                                                                                                                                                                                             |
| 10:0    | MAXPAY   | Maximum Payload.<br>The <code>USB_EPn_TXMAXP.MAXPAY</code> bits select the maximum number of bytes that may be transferred per transaction. This field can be up to 1024 but is subject to constraints by the USB specification based on endpoint mode and speed. This field should not exceed the FIFO size for the endpoint, or half the FIFO size if double buffering is used. This value should match the <code>wMaxPacketSize</code> field of the standard endpoint descriptor (USB 2.0 spec, section 9). The <code>USB_EPn_TXMAXP.MAXPAY</code> bits must be set to an even number of bytes for proper interrupt generation in DMA mode 1. |

EP0 Configuration and Status (Host) Register

The `USB_EP0_CSRn_H` register provides control and status bits for endpoint 0 in host mode. Note that some bits may be set to clear automatically.

**USB\_EP0\_CSRn\_H: EP0 Configuration and Status (Host) Register - R/W**

Reset = 0x0000

**Figure 22-69:** USB\_EP0\_CSRn\_H Register Diagram

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                             |
|---------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9       | DATGL     | Data Toggle.<br>The USB_EP0_CSRn_H.DATGL bit indicates (in host mode) the current state of the endpoint 0 data toggle. If D10 is high, this bit may be written with the required setting of the data toggle. If D10 is low, any value written to this bit is ignored. This bit is only used in host mode.                                                                                                           |
|         |           | 0 DATA0 is Set                                                                                                                                                                                                                                                                                                                                                                                                      |
|         |           | 1 DATA1 is Set                                                                                                                                                                                                                                                                                                                                                                                                      |
| 8       | FLUSHFIFO | Flush Endpoint FIFO.<br>The USB_EP0_CSRn_H.FLUSHFIFO bit directs (in host mode) the USB controller to flush data from the endpoint 0 FIFO and clear the USB_EP0_CSRn_H.TXPKTRDY and USB_EP0_CSRn_H.RXPKTRDY bits. The USB_EP0_CSRn_H.FLUSHFIFO bit should only be set if the USB_EP0_CSRn_H.TXPKTRDY and USB_EP0_CSRn_H.RXPKTRDY bits are set. Note that setting this bit at other times may cause data corruption. |
|         |           | 0 No Flush                                                                                                                                                                                                                                                                                                                                                                                                          |
|         |           | 1 Flush Endpoint FIFO                                                                                                                                                                                                                                                                                                                                                                                               |
| 7       | NAKTO     | NAK Timeout.<br>The USB_EP0_CSRn_H.NAKTO bit indicates (in host mode) when endpoint 0 is halted following the receipt of NAK responses for longer than the time set by the USB_EP0_NAKLIMITn register. The processor core should clear this bit to allow the endpoint to continue.                                                                                                                                  |
|         |           | 0 No Status                                                                                                                                                                                                                                                                                                                                                                                                         |
|         |           | 1 Endpoint Halted (NAK Timeout)                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 22-44:** USB\_EP0\_CSRn\_H Register Fields (Continued)

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                                                                                                                     |                            |
|---------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|
| 6       | STATUSPKT | Status Packet.<br>The USB_EP0_CSRn_H.STATUSPKT bit directs (in host mode) the USB controller to perform a status stage transaction. This bit is set at the same time as the USB_EP0_CSRn_H.TXPKTRDY and USB_EP0_CSRn_H.RXPKTRDY. Setting this bit ensures that the data toggle is set to 1 so that a DATA1 packet is used for the status stage transaction. |                            |
|         |           | 0                                                                                                                                                                                                                                                                                                                                                           | No Request                 |
|         |           | 1                                                                                                                                                                                                                                                                                                                                                           | Request Status Transaction |
| 5       | REQPKT    | Request Packet.<br>The USB_EP0_CSRn_H.REQPKT bit directs (in host mode) the USB controller to request an IN transaction. This bit is cleared when USB_EP0_CSRn_H.RXPKTRDY is set.                                                                                                                                                                           |                            |

The processor core should clear this bit when the packet is read from the FIFO.                                       |
|         |          | 0      No Rx Packet                                                                                                                                                                                                                                                                      |
|         |          | 1      Rx Packet in Endpoint FIFO                                                                                                                                                                                                                                                        |

## EP0 Configuration and Status (Peripheral) Register

The USB\_EP0\_CSRn\_P register provides control and status bits for endpoint 0 in peripheral mode. Note that some bits may be set to clear automatically.

**USB\_EP0\_CSRn\_P: EP0 Configuration and Status (Peripheral) Register - R/W**

Reset = 0x0000

**Figure 22-70:** USB\_EP0\_CSRn\_P Register Diagram

**Table 22-45:** USB\_EP0\_CSRn\_P Register Fields

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8       | FLUSHFIFO | Flush Endpoint FIFO.<br>The USB_EP0_CSRn_P.FLUSHFIFO bit directs (in peripheral mode) the USB controller to flush data from the endpoint 0 FIFO and clear the USB_EP0_CSRn_P.TXPKTRDY and USB_EP0_CSRn_P.RXPKTRDY bits. The USB_EP0_CSRn_P.FLUSHFIFO bit should only be set if the USB_EP0_CSRn_P.TXPKTRDY and USB_EP0_CSRn_P.RXPKTRDY bits are set. Note that setting this bit at other times may cause data corruption. |
|         |           | 0 No Flush                                                                                                                                                                                                                                                                                                                                                                                                                |
|         |           | 1 Flush Endpoint FIFO                                                                                                                                                                                                                                                                                                                                                                                                     |
| 7       | SSETUPEND | Service Setup End.<br>The USB_EP0_CSRn_P.SSETUPEND bit is set (in peripheral mode) by the processor core to clear the USB_EP0_CSRn_P.SETUPEND. This bit is cleared automatically.                                                                                                                                                                                                                                         |
|         |           | 0 No Action                                                                                                                                                                                                                                                                                                                                                                                                               |
|         |           | 1 Clear SETUPEND Bit                                                                                                                                                                                                                                                                                                                                                                                                      |

## EPn Transmit Configuration and Status (Host) Register

The USB\_EPn\_TXCSR\_H register provides (in host mode) control and status bits for transfers through the currently selected transmit endpoint.

USB\_EPn\_TXCSR\_H: EPn Transmit Configuration and Status (Host) Register - R/W

Reset = 0x0000

Figure 22-71: USB\_EPn\_TXCSR\_H Register Diagram

Table 22-46: USB\_EPn\_TXCSR\_H Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15      | AUTOSET  | TxPkJdy Autoset Enable.<br>The USB_EPn_TXCSR_H.AUTOSET bit enables (in host mode) automatic setting of the USB_EPn_TXCSR_H.TXPKTRDY bit when the maximum data packet size (USB_EPn_TXMAXP) is loaded into the transmit FIFO. The USB_EPn_TXMAXP value must be a word (4-byte) multiple. If a packet less than the maximum packet size is loaded, the USB_EPn_TXCSR_H.TXPKTRDY bit needs to be set manually. This USB_EPn_TXCSR_H.AUTOSET bit should not be set for high bandwidth endpoints (endpoints with USB_EPn_TXMAXP value greater than 1). |
|         |          | 0      Disable Autoset                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|         |          | 1      Enable Autoset                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| 7       | NAKTOINCMP | <p>NAK Timeout Incomplete.</p> <p>The USB_EPn_TXCSR_H.NAKTOINCMP bit indicates (for bulk endpoints in host mode) when the transmit endpoint is halted following the receipt of NAK responses for longer than the time set in the USB_EPn_TXINTERVAL register. The processor should clear this bit, allowing the endpoint to continue. For high-bandwidth isochronous endpoints in host mode, this bit indicates when no response is received from the device to which the packet is being sent.</p> |

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4       | SETUPPKT  | Setup Packet.<br>The USB_EPn_TXCSR_H.SETUPPKT bit directs (in host mode) the USB controller to send a SETUP token instead of an OUT token for the transaction. This bit is set at the same time as the USB_EPn_TXCSR_H.TXPKTRDY bit is set.                                                                                                                                                                                                              |
|         |           | 0 No Request                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|         |           | 1 Send SETUP Token                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 3       | FLUSHFIFO | Flush Endpoint FIFO.<br>The USB_EPn_TXCSR_H.FLUSHFIFO bit directs (in host mode) the USB controller to flush data from the endpoint FIFO and clear the USB_EPn_TXCSR_H.TXPKTRDY bit. The USB_EPn_TXCSR_H.FLUSHFIFO bit should only be set if the USB_EPn_TXCSR_H.TXPKTRDY bit is set. Note that setting this bit at other times may cause data corruption.                                                                                               |
|         |           | 0 No Flush                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|         |           | 1 Flush endpoint FIFO                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 2       | TXTOERR   | Tx Timeout Error.<br>The USB_EPn_TXCSR_H.TXTOERR bit indicates (in host mode) when three attempts have been made to send a packet and no handshake packet has been received. The USB controller generates an interrupt for this condition, clears the USB_EPn_TXCSR_H.TXPKTRDY bit, and flushes the FIFO. The processor should clear this bit. Note that USB_EPn_TXCSR_H.TXTOERR is valid only when the endpoint is operating in bulk or interrupt mode. |

|         |          | 1 Tx Packet in Endpoint FIFO                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## EPn Transmit Configuration and Status (Peripheral) Register

The USB\_EPn\_TXCSR\_P register provides (in peripheral mode) control and status bits for transfers through the currently selected transmit endpoint.

**USB\_EPn\_TXCSR\_P: EPn Transmit Configuration and Status (Peripheral) Register - R/W**

Reset = 0x0000

**Figure 22-72:** USB\_EPn\_TXCSR\_P Register Diagram

**Table 22-47:** USB\_EPn\_TXCSR\_P Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15      | AUTOSET  | TxPkrdy Autoset Enable.<br>The USB_EPn_TXCSR_P.AUTOSET bit enables (in peripheral mode) automatic setting of the USB_EPn_TXCSR_P.TXPKTRDY bit when the maximum data packet size (USB_EPn_TXMAXP) is loaded into the transmit FIFO. The USB_EPn_TXMAXP value must be a word (4-byte) multiple. If a packet less than the maximum packet size is loaded, the USB_EPn_TXCSR_P.TXPKTRDY bit needs to be set manually. This USB_EPn_TXCSR_P.AUTOSET bit should not be set for high bandwidth endpoints (endpoints with USB_EPn_TXMAXP value greater than 1). |
|         |          | 0 Disable Autoset                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|         |          | 1 Enable Autoset                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## EPn Receive Maximum Packet Length Register

The USB\_EPn\_RXMAXP register defines the maximum amount of data that can be transferred through the selected receive endpoint in a single frame.

Note that a value greater than the maximum allowed of 1023 for full-speed USB operation produces unpredictable results. Also note that the total amount of data represented by the value written to this register must not exceed the receive FIFO size, and should not exceed half the FIFO size if double-buffering is required.

**USB\_EPn\_RXMAXP: EPn Receive Maximum Packet Length Register - R/W**

Reset = 0x0000

**Figure 22-73:** USB\_EPn\_RXMAXP Register Diagram

**Table 22-48:** USB\_EPn\_RXMAXP Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                               |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 12:11   | MULTM1   | Multi-Packets per Micro-frame.<br>The USB_EPn_RXMAXP.MULTM1 bits select the number of high-speed high-bandwidth isochronous or interrupt packets that may be transferred in a microframe. The valid number of packets per microframe is 1-3 which corresponds to settings 0-2. If this field is not zero, the USB controller combines multiple packets received within a microframe into a single packet in the FIFO. |

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10:0    | MAXPAY   | Maximum Payload.<br>The USB_EPn_RXMAXP.MAXPAY bits select the maximum number of bytes that may be transferred per transaction. This field can be up to 1024 but is subject to constraints by the USB specification based on endpoint mode and speed. This field should not exceed the FIFO size for the endpoint, or half the FIFO size if double buffering is used. This value should match the wMaxPacketSize field of the standard endpoint descriptor (USB 2.0 spec, section 9). The USB_EPn_RXMAXP.MAXPAY bits must be set to an even number of bytes for proper interrupt generation in DMA mode 1. |

EPn Receive Configuration and Status (Host) Register

The USB\_EPn\_RXCSR\_H register provides (in host mode) control and status bits for transfers through the currently selected receive endpoint.

USB\_EPn\_RXCSR\_H: EPn Receive Configuration and Status (Host) Register - R/W

Reset = 0x0000

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15      | AUTOCLR  | <p>Auto Clear Enable.</p> <p>The USB_EPn_RXCSR_H.AUTOCLR bit directs (in host mode) the USB controller to automatically clear the USB_EPn_RXCSR_H.RXPkTRDY bit when a packet of size USB_EPn_RXMAXP bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, the processor must clear USB_EPn_RXCSR_H.RXPkTRDY manually. When using the DMA to unload the receive FIFO, data is read from the receive FIFO in four byte chunks, regardless of the USB_EPn_RXMAXP value. The USB controller auto clears the USB_EPn_RXCSR_H.RXPkTRDY bit as follows. (In the following: Remainder=(RxMaxP/4), and PktSz-Clearing-RxPktRdy=Actual-Bytes-Read-Packet-Sizes-That-Clear-RxPktRdy.)</p> <ul style="list-style-type: none"> <li>Remainder=0, Bytes-Read=RxMaxP, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2, RxMaxP-3</li> <li>Remainder=3, Bytes Read=RxMaxP+1, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2</li> <li>Remainder=2, Bytes Read=RxMaxP+2, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1</li> <li>Remainder=1, Bytes Read=RxMaxP+3, PktSz-Clearing-RxPktRdy=RxMaxP</li> </ul> <p>Note that the USB_EPn_RXCSR_H.AUTOCLR bit should not be set for high-bandwidth isochronous endpoints.</p> |

|         |            | 1      PID Error                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 11      | DMAREQMODE | DMA Mode Select.<br>The USB_EPn_RXCSR_H.DMAREQMODE bit selects (in host mode) between DMA request mode 1 or 0. This bit must not be cleared the cycle before or the same cycle that the USB_EPn_RXCSR_H.DMAREQEN bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention. |
|         |            | 0      DMA Request Mode 0                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## EPn Receive Configuration and Status (Peripheral) Register

The USB\_EPn\_RXCSR\_P register provides (in peripheral mode) control and status bits for transfers through the currently selected receive endpoint.

USB\_EPn\_RXCSR\_P: EPn Receive Configuration and Status (Peripheral) Register - R/W

Reset = 0x0000

Figure 22-75: USB\_EPn\_RXCSR\_P Register Diagram

**Table 22-50:** USB\_EPn\_RXCSR\_P Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15      | AUTOCLR  | <p>Auto Clear Enable.</p> <p>The USB_EPn_RXCSR_P.AUTOCLR bit directs (in peripheral mode) the USB controller to automatically clear the USB_EPn_RXCSR_P.RXPkTRDY bit when a packet of size USB_EPn_RXMAXP bytes has been unloaded from the receive FIFO. When packets of less than the maximum packet size are unloaded, the processor must clear USB_EPn_RXCSR_P.RXPkTRDY manually. When using the DMA to unload the receive FIFO, data is read from the receive FIFO in four byte chunks, regardless of the USB_EPn_RXMAXP value. The USB controller auto clears the USB_EPn_RXCSR_P.RXPkTRDY bit as follows. (In the following: Remainder=(RxMaxP/4), and PktSz-Clearing-RxPktRdy=Actual-Bytes-Read-Packet-Sizes-That-Clear-RxPktRdy.)</p> <ul style="list-style-type: none"> <li>• Remainder=0, Bytes-Read=RxMaxP, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2, RxMaxP-3</li> <li>• Remainder=3, Bytes Read=RxMaxP+1, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1, RxMaxP-2</li> <li>• Remainder=2, Bytes Read=RxMaxP+2, PktSz-Clearing-RxPktRdy=RxMaxP, RxMaxP-1</li> <li>• Remainder=1, Bytes Read=RxMaxP+3, PktSz-Clearing-RxPktRdy=RxMaxP</li> </ul> <p>Note that the USB_EPn_RXCSR_P.AUTOCLR bit should not be set for high-bandwidth isochronous endpoints.</p> |
|         |          | 0      Disable Auto Clear                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|         |            | 0      Disable DMA Request                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|         |            | 1      Enable DMA Request                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 12      | DNYETPERR  | Disable NYET Handshake.<br>The USB_EPn_RXCSR_P.DNYETPERR bit disables (in peripheral mode for high speed bulk/interrupt transactions) NYET handshakes. When this bit is set, all successful receive packets are ACK'd, including the point at which the FIFO becomes full. The USB_EPn_RXCSR_P.DNYETPERR bit must be set for all interrupt endpoints in high speed mode.                                                                                                      |
|         |            | 0      Enable NYET Handshake                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|         |            | 1      Disable NYET Handshake                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 11      | DMAREQMODE | DMA Mode Select.<br>The USB_EPn_RXCSR_P.DMAREQMODE bit selects (in peripheral mode) between DMA request mode 1 or 0. This bit must not be cleared the cycle before or the same cycle that the USB_EPn_RXCSR_P.DMAREQEN bit is cleared. In DMA request mode 0, the DMA is programmed to load one packet at a time. Processor intervention is required for each packet. DMA mode 1 can be used with bulk endpoints to transmit multiple packets without processor intervention. |
|         |            | 0      DMA Request Mode 0                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|         |            | 1      DMA Request Mode 1                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 8       | INCOMPRX   | Incomplete Rx.<br>The USB_EPn_RXCSR_P.INCOMPRX bit indicates (in peripheral mode for high-bandwidth isochronous or interrupt transfers) when the received packet is incomplete because parts of the packet were not received. This bit is cleared when USB_EPn_RXCSR_P.RXPKTRDY is cleared. For all other modes, this bit is zero.                                                                                                                                            |
|         |            | 0      No Status                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|         |            | 1      Incomplete Rx                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| 7       | CLRDATATGL | Clear Endpoint Data Toggle.<br>The USB_EPn_RXCSR_P.CLRDATATGL bit is set (in peripheral mode) by the processor to reset the endpoint data toggle to 0.                                                                                                                                                                                                           |
|         |            | 0                      No Action                                                                                                                                                                                                                                                                                                                                 |
|         |            | 1                      Reset EP Data Toggle to 0                                                                                                                                                                                                                                                                                                                 |
| 6       | SENTSTALL  | Sent STALL.<br>The USB_EPn_RXCSR_P.SENTSTALL bit indicates (in peripheral mode) when a STALL handshake is transmitted. The processor should clear this bit.                                                                                                                                                                                                      |
|         |            | 0                      No Status                                                                                                                                                                                                                                                                                                                                 |
|         |            | 1                      STALL Handshake Transmitted                                                                                                                                                                                                                                                                                                               |
| 5       | SENDSTALL  | Send STALL.<br>The USB_EPn_RXCSR_P.SENDSTALL bit is set (in peripheral mode) by the processor to send a STALL handshake. The processor clears this bit to terminate the stall condition. This bit has no effect for isochronous transfers.                                                                                                                       |
|         |            | 0                      No Action                                                                                                                                                                                                                                                                                                                                 |
|         |            | 1                      Request STALL Handshake                                                                                                                                                                                                                                                                                                                   |
| 4       | FLUSHFIFO  | Flush Endpoint FIFO.<br>The USB_EPn_RXCSR_P.FLUSHFIFO bit directs (in peripheral mode) the USB controller to flush data from the endpoint FIFO and clear the USB_EPn_RXCSR_P.RXPKTRDY bit. The USB_EPn_RXCSR_P.FLUSHFIFO bit should only be set if the USB_EPn_RXCSR_P.RXPKTRDY bit is set. Note that setting this bit at other times may cause data corruption. |
|         |            | 0                      No Flush                                                                                                                                                                                                                                                                                                                                  |
|         |            | 1                      Flush Endpoint FIFO                                                                                                                                                                                                                                                                                                                       |

**Table 22-50:** USB\_EPn\_RXCSR\_P Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                    |                            |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|
| 3       | DATAERR  | Data Error.<br>The USB_EPn_RXCSR_P.DATAERR bit indicates (in peripheral mode for isochronous transfers) when the USB_EPn_RXCSR_P.RXPKTRDY bit is set and the data packet has a CRC or bit-stuff error. This bit is cleared when USB_EPn_RXCSR_P.RXPKTRDY is cleared. The USB_EPn_RXCSR_P.DATAERR bit is always zero for bulk endpoints in peripheral mode. |                            |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                          | No Status                  |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                          | Data Error                 |
| 2       | ORUNERR  | OUT Run Error.<br>The USB_EPn_RXCSR_P.ORUNERR bit indicates (in peripheral mode for isochronous transfers) when an OUT packet cannot be loaded into the receive FIFO. The processor should clear this bit. The USB_EPn_RXCSR_P.ORUNERR bit always returns zero in bulk mode.                                                                               |                            |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                          | No Status                  |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                          | OUT Run Error              |
| 1       | FIFOFULL | FIFO Full.<br>The USB_EPn_RXCSR_P.FIFOFULL bit indicates (in peripheral mode) when no more packets can be loaded into the receive FIFO.                                                                                                                                                                                                                    |                            |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                          | No Status                  |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                          | FIFO Full                  |
| 0       | RXPKTRDY | Rx Packet Ready.<br>The USB_EPn_RXCSR_P.RXPKTRDY is set (in peripheral mode) when a data packet is received. An interrupt is generated (if enabled) when this bit is set. The processor core should clear this bit when the packet is read from the FIFO.                                                                                                  |                            |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                          | No Rx Packet               |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                          | Rx Packet in Endpoint FIFO |

## EP0 Number of Received Bytes Register

The USB\_EP0\_CNTn register indicates the number of received data bytes in the endpoint 0 FIFO. The value returned changes as the contents of the FIFO change and is only valid while the USB\_EP0\_CSRn\_H.RXPKT RDY bit or USB\_EP0\_CSRn\_P.RXPKT RDY bit is set.

USB\_EP0\_CNTn: EP0 Number of Received Bytes Register - R/NW

Reset = 0x0000

Figure 22-76: USB\_EP0\_CNTn Register Diagram

Table 22-51: USB\_EP0\_CNTn Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6:0     | RXCNT    | Rx Byte Count Value.<br>The USB_EP0_CNTn.RXCNT bits holds the number of data bytes currently inline ready to be read from the Rx FIFO. The value returned changes as the FIFO is unloaded and is only valid while USB_EP0_CSRn_H.RXPKT RDY bit or USB_EP0_CSRn_P.RXPKT RDY bit is set. |

## EPn Number of Bytes Received Register

The USB\_EPn\_RXCNT register indicates the number of received data bytes in the endpoint receive FIFO. The value returned changes as the contents of the FIFO change and is only valid while the USB\_EPn\_RXCSR\_H.RXPKT RDY bit or USB\_EPn\_RXCSR\_P.RXPKT RDY bit is set.

USB\_EPn\_RXCNT: EPn Number of Bytes Received Register - R/NW

Reset = 0x0000

Table 22-52: USB\_EPn\_RXCNT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                              |
|---------|----------|----------------------------------------------------------------------------------------------------------------------|
| 13:0    | EPRXCNT  | EP Rx Count.<br>The USB_EPn_RXCNT.EPRXCNT bits hold the number of data bytes ready to be read from the receive FIFO. |

EPn Transmit Type Register

The USB\_EPn\_TXTYPE register selects the endpoint number and transaction protocol to use for the currently selected transmit endpoint. There is a USB\_EPn\_TXTYPE register for each transmit endpoint. Note that this register is only used in host mode.

Figure 22-78: USB\_EPn\_TXTYPE Register Diagram

**Table 22-53:** USB\_EPn\_TXTYPE Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:6     | SPEED    | Speed of Operation Value.<br>The USB_EPn_TXTYPE.SPEED bits select the USB controller operating speed for the endpoint when acting as a host connected to devices through a hub. In these instances, the USB controller must issue split transactions under certain conditions. If a device is directly connected (not through a hub), all endpoints use the same speed as which the controller is connected. When not connected to devices through a hub, program this field with 00. |
|         |          | 0 Same Speed as the Core                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## EP0 Connection Type Register

The USB\_EP0\_TYPE<sub>n</sub> register selects the USB controller operating speed for endpoint 0 when acting as a host connected to devices through a hub.

USB\_EP0\_TYPEn: EP0 Connection Type Register - R/W

Reset = 0x00

Figure 22-79: USB\_EP0\_TYPEn Register Diagram

|         |          | 3 Low Speed                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

EP0 NAK Limit Register

The USB\_EP0\_NAKLIMITn register determines the number of frames/micro-frames after which endpoint 0 should timeout on receiving a stream of NAK responses for bulk endpoints.

USB\_EP0\_NAKLIMITn: EP0 NAK Limit Register - R/W

Reset = 0x00

Figure 22-80: USB\_EP0\_NAKLIMITn Register Diagram

**Table 22-55:** USB\_EP0\_NAKLIMITn Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                         |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------|
| 4:0     | VALUE    | Endpoint 0 Timeout Value (in Frames).<br>The USB_EP0_NAKLIMITn.VALUE bits hold the endpoint 0 timeout value (number of frames). |

**EPn Transmit Polling Interval Register**

The USB\_EPn\_TXINTERVAL register defines the polling interval for the currently selected transmit endpoint for interrupt, isochronous, and bulk transfers. There is a USB\_EPn\_TXINTERVAL register for each configured transmit endpoint, except endpoint 0. The transfer types relate to speed, interval value, and interval operation as follows:

- Interrupt: Speed=Low Speed or Full Speed, USB\_EPn\_TXINTERVAL=1-255, and Operation=Polling interval is m frames.
- Interrupt: Speed=High Speed, USB\_EPn\_TXINTERVAL=1-16, and Operation=Polling interval is 2<sup>(m-1)</sup> micro-frames.
- Isochronous: Speed=Full Speed or High Speed, USB\_EPn\_TXINTERVAL=1-16, and Operation=Polling interval is 2<sup>(m-1)</sup> frames or micro-frames.
- Bulk: Speed=Full Speed or High Speed, USB\_EPn\_TXINTERVAL=2-16, and Operation=NAK Limit is 2<sup>(m-1)</sup> frames or micro-frames.

Note that a USB\_EPn\_TXINTERVAL value of 0 or 1 disables the NAK timeout function.

**USB\_EPn\_TXINTERVAL: EPn Transmit Polling Interval Register - R/W**

Reset = 0x00

**Table 22-56:** USB\_EPn\_TXINTERVAL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | VALUE    | <p>Tx Polling Interval.</p> <p>The <code>USB_EPn_TXINTERVAL.VALUE</code> bits define the polling interval value for interrupt and isochronous transfers and select the number of frames/microframes after which the endpoint should timeout on receiving a stream of NAK responses for bulk and control endpoints. Note that the USB controller halts transfers to control endpoints if the host receives NAK responses for more frames than the limit set by this register.</p> |

## EPn Receive Type Register

The `USB_EPn_RXTYPE` register selects the endpoint number and transaction protocol to use for the currently selected receive endpoint. There is a `USB_EPn_RXTYPE` register for each receive endpoint. Note that this register is only used in host mode.

### USB\_EPn\_RXTYPE: EPn Receive Type Register - R/W

If a device is directly connected (not through a hub), all endpoints use the same speed as which the controller is connected. When not connected to devices through a hub, program this field with 00. |
|         |          | 0 Same Speed as the Core                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                  |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3:0     | TGTEP    | Target Endpoint Number.<br>The USB_EPn_RXTYPE.TGTEP bits select (for endpoints 1-11) the target endpoint. This value should be set to the endpoint number contained in the receive endpoint descriptor returned during device enumeration. Endpoint 0 always uses target endpoint number 0. (Enumeration values not shown are reserved.) |
|         |          | 0 Endpoint 0                                                                                                                                                                                                                                                                                                                             |
|         |          | 1 Endpoint 1                                                                                                                                                                                                                                                                                                                             |

## EPn Receive Polling Interval Register

The USB\_EPn\_RXINTERVAL register defines the polling interval for the currently selected receive endpoint for interrupt, isochronous, and bulk transfers. There is a USB\_EPn\_RXINTERVAL register for each config-

ured receive endpoint, except endpoint 0. The transfer types relate to speed, interval value, and interval operation as follows:

- Interrupt: Speed=Low Speed or Full Speed, USB\_EPn\_RXINTERVAL=1-255, and Operation=Polling interval is m frames.
- Interrupt: Speed=High Speed, USB\_EPn\_RXINTERVAL=1-16, and Operation=Polling interval is  $2^{(m-1)}$  micro-frames.
- Isochronous: Speed=Full Speed or High Speed, USB\_EPn\_RXINTERVAL=1-16, and Operation=Polling interval is  $2^{(m-1)}$  frames or micro-frames.
- Bulk: Speed=Full Speed or High Speed, USB\_EPn\_RXINTERVAL=2-16, and Operation=NAK Limit is  $2^{(m-1)}$  frames or micro-frames.

Note that a USB\_EPn\_RXINTERVAL value of 0 or 1 disables the NAK timeout function.

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | VALUE    | Rx Polling Interval.<br>The USB_EPn_RXINTERVAL.VALUE bits define the polling interval value for interrupt and isochronous transfers and select the number of frames/microframes after which the endpoint should timeout on receiving a stream of NAK responses for bulk and control endpoints. Note that the USB controller halts transfers to control endpoints if the host receives NAK responses for more frames than the limit set by this register. |

EP0 Configuration Information Register

The USB\_EP0\_CFGDATA<sub>n</sub> register describes the USB controller hardware configuration. This register only exists for endpoint 0.

**USB\_EP0\_CFGDATAn: EP0 Configuration Information Register - R/NW**

## DMA Interrupt Register

The USB\_DMA\_IRQ register indicates which of the DMA master channels have a pending interrupt. The USB controller generates the interrupt when the corresponding DMA count register (USB\_DMA<sub>n</sub>\_CNT) reaches zero. The USB controller clears this register when it is read.

**USB\_DMA\_IRQ: DMA Interrupt Register - R/NW**

Reset = 0x00

## DMA Channel n Control Register

There is a `USB_DMAn_CTL` register for each DMA master channel. This register assigns, configures, and controls each endpoint with a corresponding DMA master channel.

USB\_DMAn\_CTL: DMA Channel n Control Register - R/W

Reset = 0x0000

Figure 22-86: USB\_DMAn\_CTL Register Diagram

Table 22-61: USB\_DMAn\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                     |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10:9    | BRSTM    | Burst Mode.<br>The USB_DMAn_CTL . BRSTM bits select the type or length of burst transfer used by the corresponding DMA channel to transfer data.            |
|         |          | 0 Unspecified Length                                                                                                                                        |

## DMA Channel n Address Register

The USB\_DMA<sub>n</sub>\_ADDR register indicates the location in on-chip memory where DMA data is written or read. The address must be aligned to 32-bit words (The lower two address bits are always zero.) This register increments as the DMA transfer progresses.

USB\_DMAn\_ADDR: DMA Channel n Address Register - R/W

Reset = 0x0000 0000

Table 22-62: USB\_DMAn\_ADDR Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                         |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | VALUE    | DMA Address Value.<br>The USB_DMAn_ADDR.VALUE bits hold the address value for the location in on-chip memory where DMA data is written or read. |

DMA Channel n Count Register

The USB\_DMAn\_CNT register holds the DMA count, indicating the number of bytes to be transferred for a given DMA work block. If this field is set to zero, no data is transferred, and an interrupt is generated.

USB\_DMAn\_CNT: DMA Channel n Count Register - R/W

Reset = 0x0000 0000

Figure 22-88: USB\_DMAn\_CNT Register Diagram

Table 22-63: USB\_DMA<sub>n</sub>\_CNT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                 |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | VALUE    | DMA Count Value.<br>The USB_DMA <sub>n</sub> _CNT.VALUE bits indicate the number of bytes to be transferred for a given DMA work block. |

EP<sub>n</sub> Request Packet Count Register

The USB\_RQPKTCNT<sub>n</sub> register specifies (in host mode) the number of packets to request in a block transfer of one or more bulk packets of size USB\_EP<sub>n</sub>\_RXMAXP from a receive endpoint. This register only applies for receive endpoints 1 through 11 in host mode.

USB\_RQPKTCNT<sub>n</sub>: EP<sub>n</sub> Request Packet Count Register - R/W

Reset = 0x0000

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                 |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0    | VALUE    | Request Packet Count Value.<br>The USB_RQPKTCNT <sub>n</sub> .VALUE bits specify the number of bulk packets to request in a block transfer from a receive endpoint. This field is used in conjunction with Auto Request feature (USB_EP <sub>n</sub> _RXCSR_H.AUTOREQ). |

Chirp Timeout Register

The USB\_CT\_UCH register selects chirp timeout value. The is value is multiplied by 4 times the XCLK period (or 67ns). The default setting is 1.1ms.

USB\_CT\_UCH: Chirp Timeout Register - R/W

Reset = 0x4074

| 14:0    | VALUE    | Chirp Timeout Value.<br>The USB_CT_UCH.VALUE bits select the chirp timeout value. |

Host High Speed Return to Normal Register

The USB\_CT\_HHSRTN register selects the delay from end of high speed resume signaling (acting as a host) to return to normal mode operation. This value is multiplied by 4 times the XCLK period (or 16.7ns). The default setting corresponds to a delay of 100us.

USB\_CT\_HHSRTN: Host High Speed Return to Normal Register - R/W

Reset = 0x05e6

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14:0    | VALUE    | Host High Speed Return to Normal Value.<br>The USB_CT_HHSRTN register selects the delay from end of high speed resume signaling (acting as a host) to return to normal mode operation. |

## High Speed Timeout Register

The `USB_CT_HSBT` register selects an amount of time to add to the minimum high speed timeout in units of 64 bit times. The USB 2.0 specification section 7.1.19.2 states that the controller must not timeout less than 736 bit times and must timeout after 816 bit times. The value in `USB_CT_HSBT` is multiplied by 64-bit times and added to the minimum 736 bit times. Settings less than 1 violate the USB 2.0 specification, making the controller non-compliant.

Figure 22-92: USB\_CT\_HSBT Register Diagram

Table 22-67: USB\_CT\_HSBT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                   |

| 3:0     | VALUE    | HS Timeout Adder.<br>The <code>USB_CT_HSBT.VALUE</code> bits selects an amount of time to add to the minimum high speed timeout in units of 64 bit times. |
|         |          | 0 HS Timeout = 736 (bit time)                                                                                                                             |
|         |          | 1 HS Timeout = 800 (bit time)                                                                                                                             |
|         |          | 2 HS Timeout = 864 (bit time)                                                                                                                             |

## LPM Attribute Register

The `USB_LPM_ATTR` register defines the link power management (LPM) attributes for LPM transactions and sleep/wake operation. In peripheral mode, the `USB_LPM_ATTR` register contains values received in the most recent, accepted (ACK'd) LPM transaction. In host mode, the `USB_LPM_ATTR` register contains values (loaded by software) that set up the next LPM transaction. The USB controller inserts the LPM values within the next LPM transaction.

**USB\_LPM\_ATTR: LPM Attribute Register - R/W**

Reset = 0x0000

**Figure 22-93:** USB\_LPM\_ATTR Register Diagram

**Table 22-68:** USB\_LPM\_ATTR Register Fields

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                       |
|---------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:12   | EP        | Endpoint.<br>The <code>USB_LPM_ATTR.EP</code> bits select the endpoint in the token packet of the LPM transaction.                                                                                                                                                                                                                                                                                            |
| 8       | RMTWAK    | Remote Wakeup Enable.<br>The <code>USB_LPM_ATTR.RMTWAK</code> bit enables remote wakeup. This bit is applied on a temporary basis only and is only applied to the current suspend state. After the current suspend cycle, the remote wakeup capability that was negotiated during enumeration applies.                                                                                                        |
|         | 0         | Disable Remote Wakeup                                                                                                                                                                                                                                                                                                                                                                                         |
|         | 1         | Enable Remote Wakeup                                                                                                                                                                                                                                                                                                                                                                                          |
| 7:4     | HIRD      | Host Initiated Resume Duration.<br>The <code>USB_LPM_ATTR.HIRD</code> bits select the host initiated resume duration. This value is the minimum time that the host drives resume on the bus. The value in this register corresponds to an actual resume time of:<br>$\text{Resume Time} = 50\mu\text{s} + \text{HIRD} \times 75\mu\text{s}$ .<br>This equation produces results in a range of 50us to 1200us. |
| 3:0     | LINKSTATE | Link State.<br>The <code>USB_LPM_ATTR.LINKSTATE</code> bits is value is provided by the host to the peripheral to indicate what state the peripheral must transition to after the receipt and acceptance of a LPM transaction. (Enumerations not shown are reserved.)                                                                                                                                         |
|         | 1         | Sleep State (L1)                                                                                                                                                                                                                                                                                                                                                                                              |

## LPM Control Register

The USB\_LPM\_CTL register controls link power management (LPM) operations, including LPM enable, NAK, resume, and mode transition.

Figure 22-94: USB\_LPM\_CTL Register Diagram

Table 22-69: USB\_LPM\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                           |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4       | NAK      | LPM NAK Enable.<br>The USB_LPM_CTL.NAK bit enables (in peripheral mode) a NAK-all-non-LPM transactions mode for all end points, forcing a NAK response to all transactions other than an LPM transaction. This bit only takes effect after the controller has been LPM suspended. In this case, the USB controller continues to NAK, until this bit has been cleared by software. |
|         |          | 0      Disable LPM NAK                                                                                                                                                                                                                                                                                                                                                            |
|         |          | 1      Enable LPM NAK                                                                                                                                                                                                                                                                                                                                                             |

**Table 22-69:** USB\_LPM\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

The USB controller responds to an LPM transaction with a STALL.                                                                                                                                                                                                                                                                                                                                   |
|         |          | 3<br>Enable LPM and Extended Transactions<br>Both LPM and extended transactions are supported. The USB controller responds with a NYET or an ACK as determined by the value of <code>LPMXMT</code> and other conditions.                                                                                                                                                                                                                                                                              |
| 1       | RESUME   | LPM Resume (Remote Wakeup).<br>The <code>USB_LPM_CTL.RESUME</code> bit initiates resume (remote wakeup). This bit's operation differs from the <code>USB_POWER.RESUME</code> bit in that the LPM resume signal timing is controlled by hardware. When set, the USB controller asserts resume signaling for 50us in host mode or asserts resume signaling for the time specified by the <code>USB_LPM_ATTR.HIRD</code> field in device mode. The <code>USB_LPM_CTL.RESUME</code> bit is self clearing. |
|         |          | 0<br>No Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|         |          | 1<br>LPM Resume                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| 0       | TX       | <p>.</p> <p>The USB_LPM_CTL.TX bit puts the USB controller in LPM transmit mode, but this mode has differing operations in host mode versus peripheral mode.</p> <p>In peripheral mode, this bit is set by software to instruct the controller to transition to the L1 state upon receipt of the next LPM transaction. This bit is only effective if LPM enable (USB_LPM_CTL.EN) is set to 0x3. The LPM transmit enable bit can be set in the same cycle as LPM enable. If USB_LPM_CTL.TX and USB_LPM_CTL.EN are enabled, the USB controller can respond in the following ways:</p> <ul style="list-style-type: none"><li>• If no data is pending (all transmit FIFOs are empty), the USB controller responds with an ACK, clears the USB_LPM_CTL.TX bit, and generates a software interrupt.</li><li>• If data is pending (data resides in at least one transmit FIFO), the USB controller responds with a NYET, does not clear the USB_LPM_CTL.TX bit, and generates a software interrupt.</li></ul> <p>In host mode, this bit is set by software to transmit an LPM transaction. This bit is self clearing. The USB controller clears this bit immediately on receipt of any token or after three timeouts have occurred.</p> |                |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Disable LPM Tx |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Enable LPM Tx  |

## LPM Interrupt Enable Register

The USB\_LPM\_IEN register enables the link power management (LPM) related interrupts. When an interrupt is enabled in this register and the corresponding interrupt is pending in USB\_LPM\_IRQ, the USB controller generates the interrupt. When an interrupt is disabled in this register, the corresponding interrupt may be pending in USB\_LPM\_IRQ, but the USB controller does not generate an interrupt.

**USB\_LPM\_IEN: LPM Interrupt Enable Register - R/W**

Reset = 0x00

**Figure 22-95:** USB\_LPM\_IEN Register Diagram

**Table 22-70:** USB\_LPM\_IEN Register Fields

| Bit No. | Bit Name | Description/Enumeration            |                   |
|---------|----------|------------------------------------|-------------------|
| 5       | LPMERR   | LPM Error Interrupt Enable.        |                   |
|         |          | 0                                  | Disable Interrupt |
|         |          | 1                                  | Enable Interrupt  |
| 4       | LPMRES   | LPM Resume Interrupt Enable.       |                   |
|         |          | 0                                  | Disable Interrupt |
|         |          | 1                                  | Enable Interrupt  |
| 3       | LPMNC    | LPM NYET Control Interrupt Enable. |                   |
|         |          | 0                                  | Disable Interrupt |
|         |          | 1                                  | Enable Interrupt  |
| 2       | LPMACK   | LPM ACK Interrupt Enable.          |                   |

|         |          | 1                                  | Enable Interrupt  |

Table 22-70: USB\_LPM\_IEN Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration     |
|---------|----------|-----------------------------|
| 1       | LPMNY    | LPM NYET Interrupt Enable.  |
|         |          | 0 Disable Interrupt         |
|         |          | 1 Enable Interrupt          |
| 0       | LPMST    | LPM STALL Interrupt Enable. |
|         |          | 0 Disable Interrupt         |
|         |          | 1 Enable Interrupt          |

LPM Interrupt Status Register

The USB\_LPM\_IRQ register indicates link power management (LPM) related interrupt status. The USB controller clears this register when it is read.

USB\_LPM\_IRQ: LPM Interrupt Status Register - R/NW

Reset = 0x00

| 3       | LPMNC    | <p>LPM NYET Control Interrupt.</p> <p>The <code>USB_LPM_IRQ.LPMNC</code> bit indicates an LPM NYET control interrupt condition, but this interrupt has differing conditions for host mode versus peripheral mode.</p> <p>In peripheral mode, this bit is set when an LPM transaction is received, and the USB controller responds with a NYET due to data pending in the transmit FIFOs. This interrupt may only occur when the <code>USB_LPM_CTL.EN</code> field is set to 11, the <code>USB_LPM_CTL.TX</code> field is set to 1, and there is data pending in the transmit FIFOs.</p> <p>In host mode, this bit is set when an LPM transaction has been transmitted, but has failed to complete. The transaction failure must be because a timeout occurred or be because there were bit errors in the response for three attempts.</p> |                      |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | No Interrupt Pending |

|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Interrupt Pending    |

## LPM Function Address Register

The `USB_LPM_FADDR` register selects the link power management (LPM) function address.

**USB\_LPM\_FADDR: LPM Function Address Register - R/W**

Reset = 0x00

**Figure 22-97:** USB\_LPM\_FADDR Register Diagram

Table 22-72: USB\_LPM\_FADDR Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                        |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 6:0     | VALUE    | Function Address Value.<br>The USB_LPM_FADDR.VALUE bits hold the LPM function address value that the USB controller places in the LPM payload. |

VBUS Control Register

The USB\_VBUS\_CTL controls USB controller VBUS related features.

USB\_VBUS\_CTL: VBUS Control Register - R/W

Reset = 0x00

Figure 22-98: USB\_VBUS\_CTL Register Diagram

Table 22-73: USB\_VBUS\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                          |
|---------|----------|------------------------------------------------------------------------------------------------------------------|
| 4       | DRV      | VBUS Drive.<br>The USB_VBUS_CTL.DRV bit indicates the state of the UTMI+ DrvVBUS signal from the USB controller. |
| 3       | DRVINT   | VBUS Drive Interrupt.<br>The USB_VBUS_CTL.DRVINT bit indicates the state of the DrvVBUSInt interrupt.            |
| 2       | DRVIE    | VBUS Drive Interrupt Enable.<br>The USB_VBUS_CTL.DRVIE bit enables the DrvVBUS interrupt.                        |
| 1       | DRVOD    | VBUS Drive Open Drain.<br>The USB_VBUS_CTL.DRVOD selects whether the DrvVBUS output is open drain.               |

**Table 22-73:** USB\_VBUS\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                             |
|---------|----------|-----------------------------------------------------------------------------------------------------|
| 0       | INVDRV   | VBUS Invert Drive.<br>The USB_VBUS_CTL . INVDRV bit selects whether the DrvVBUS output is inverted. |

## Battery Charging Control Register

The USB\_BAT\_CHG controls USB controller battery changing related features.

**USB\_BAT\_CHG: Battery Charging Control Register - R/W**

Reset = 0x00

**Figure 22-99:** USB\_BAT\_CHG Register Diagram

**Table 22-74:** USB\_BAT\_CHG Register Fields

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                                                                                                                  |
|---------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4       | DEDCHG    | Dedicated Charging Port.<br>The USB_BAT_CHG . DEDCHG bit is asserted if both D+ and D- are high. This can be used to determine if the attached device is a dedicated charging port. This bit is the decode of LineState[1] and LineState[0]. This bit is only valid when a session is initiated, which enables a pullup on D+ when acting as a B-device. |
| 3       | CHGDET    | Charging Port Detected.<br>The USB_BAT_CHG . CHGDET bit indicates when a charging port is detected. This bit indicates that D+/- is above $V_{DAT\_REF}$ and below $V_{LGC}$ .                                                                                                                                                                           |
| 2       | SNSCHGDET | Sense Charger Detection.<br>The USB_BAT_CHG . SNSCHGDET bit enables charger detection. Setting this bit enables VD_SRC and ID_SINK.                                                                                                                                                                                                                      |

Table 22-74: USB\_BAT\_CHG Register Fields (Continued)

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                     |
|---------|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1       | CONDET    | Connected Detected.<br>The USB_BAT_CHG.CONDET bit is valid when USB_BAT_CHG.SNSCONDET is enabled. This bit reflects the inverse of D+ (!LineState[0]). If nothing is connected, D+ is pulled high. If a charger or USB port is connected, D+ is pulled low. |
| 0       | SNSCONDET | Sense Connection Detection.<br>The USB_BAT_CHG.SNSCONDET bit enables connection detection. Enabling this bit enables I <sub>DP_SRC</sub> and R <sub>DM_DWN</sub> .                                                                                          |

PHY Control Register

The USB\_PHY\_CTL register provides access to PHY control features.

USB\_PHY\_CTL: PHY Control Register - R/W

Reset = 0x00

Figure 22-100: USB\_PHY\_CTL Register Diagram

Table 22-75: USB\_PHY\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                      |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7       | EN       | PHY Enable.<br>The USB_PHY_CTL.EN bit enables the USB controller PHY. This bit enables the schmitt-trigger inputs on D+ and D- to detect session request protocol. The bit also enables the bias circuits and VBUS comparators to detect when a host is connected. This bit should be set for all USB controller operations. |

**Table 22-75:** USB\_PHY\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                 |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1       | RESTORE  | Restore from Hibernate.<br>The USB_PHY_CTL.RESTORE bit causes the PHY to come out of hibernate and release its latches.                                 |
| 0       | HIBER    | Hibernate.<br>The USB_PHY_CTL.HIBER bit causes the PHY to prepare for hibernate. Latches hold the pullup/pulldown state when the core power is removed. |

## PLL and Oscillator Control Register

The USB\_PLL\_OSC register provides access to PLL and oscillator related control features.

**USB\_PLL\_OSC: PLL and Oscillator Control Register - R/W**

Reset = 0x0014

**Figure 22-101:** USB\_PLL\_OSC Register Diagram

**Table 22-76:** USB\_PLL\_OSC Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                             |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7       | PLLMSEL  | PLL Multiplier Select.<br>The USB_PLL_OSC.PLLMSEL bit directs the PLL to use the PLL multiplier value is stored the USB_PLL_OSC.PLLM bits.                                                                                          |
| 6:1     | PLLM     | PLL Multiplier Value.<br>The USB_PLL_OSC.PLLM bits hold the PLL multiplier value. This field should be set such that $\text{CLKIN} * \text{USB\_PLL\_OSC.PLLM} = 480\text{MHz}$ . Defaults to $48\text{MHz} * 10 = 480\text{MHz}$ . |

| Bit No. | Bit Name | Description/Enumeration                                                                                      |
|---------|----------|--------------------------------------------------------------------------------------------------------------|
| 0       | DIVCLKIN | Divide CLKIN.<br>The <code>USB_PLL_OSC.DIVCLKIN</code> bit enables a divide CLKIN by 2 function for the PLL. |

# 23 Ethernet Media Access Controller (EMAC)

This chapter describes the Ethernet Media Access Controller (EMAC) peripheral. The Ethernet MAC provides a 10/100M bit/s Ethernet interface, compliant to IEEE Std. 802.3-2005, between an RMII (Reduced Media Independent Interface) and the processor.

## Overview

The processor has two identical and independent EMAC peripheral modules, which enables network connectivity to applications via a 10/100M bit/s Ethernet interface. The modules are fully compliant to the following standards:

- Carrier Sense Multiple Access With Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications, Standard 802.3-2005, Institute of Electrical and Electronics Engineers (IEEE).
- Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control Systems, Standard 1588-2008, Institute of Electrical and Electronics Engineers (IEEE).
- Reduced Media Independent Interface Specification, Revision 1.2, RMII Consortium.

**NOTE:** Copyright © 2010 Synopsys, Inc.; portions of this chapter are included with permission from Synopsys, Inc.

## Introduction

The EMAC interface consists of necessary hardware for the Media Access Control protocol enabling applications to support TCP/IP based network communication. At the system end, the module supports direct hook up with the System Crossbar bus for Memory/MMR transactions. It supports RMII (Reduced Media Independent Interface) and SMI (Station Management Interface) for interfacing with the external PHY chip.

The MAC also includes a built-in and dedicated DMA controller that performs both data and status transfers between the application and the RMII interface. Internal transmit and receive FIFOs are used to buffer and regulate the frames. A dedicated interrupt line connects the EMAC interrupt sources to the System Event Controller.

The MAC Management Counters (MMC) block is an extended set of registers that collect various statistics compliant with IEEE 802.3 definitions regarding the operation of the interface. They are updated for each new transmitted or received frame when the condition to update the counter is met. The EMAC provides a set of such counters, along with extended usage control.

The EMAC also includes a PTP (Precision Time Protocol) engine that provides hardware assistance for the implementation of the IEEE 1588 Version 1 and Version 2 standards on Blackfin processors, enabling time synchronization between systems.

## EMAC Features

The ethernet MAC's features include the following:

- Supports 10/100 Mbps data transfer rates with external PHY interfaced via RMII.
- Full-Duplex and Half-Duplex support for Ethernet.
- Dedicated DMA controller with independent read write channels.
- Supports dual-buffer (ring) or linked-list (chained) descriptor chaining.
- Direct interface with the System Crossbar bus.
- Provides support for CSMA/CD Protocol for half-duplex operation.
- IEEE 802.3x flow control for Full-Duplex and Half-Duplex.
- Automatic network monitoring statistics with Management Counters.
- Flexible address filtering options for uni-cast/multi-cast/broadcast addresses.
- Support for Promiscuous mode in reception.
- Supports IEEE 802.1Q VLAN tag detection.
- Supports programmable Inter-frame Gap (IFG).
- Checksum Offload Engine for checking IPv4 header checksum and TCP/UDP/ICMP checksum encapsulated in IPv4 or IPv6 datagrams.
- Station Management Interface for PHY device configuration and management.
- Includes FIFOs for buffering: 256 bytes for transmit FIFO and 128 bytes for receive FIFO.
- Automatic CRC and pad generation controllable on a per-frame basis.

## EMAC Functional Description

This section details the functionality of Ethernet MAC peripheral. Sub sections are provided detailing each topic in-depth.

## EMAC Register List

The ethernet MAC (EMAC) module provides a 10/100M bit/s Ethernet interface, compliant to IEEE Std. 802.3-2005, between an RMII (Reduced Media Independent Interface) and the Blackfin processor. A set of registers govern EMAC operations. For more information on EMAC functionality, see the EMAC register descriptions.

**Table 23-1:** EMAC Module Registers

| Name            | Description                  |
|-----------------|------------------------------|
| EMAC_MACCFG     | MAC Configuration Register   |
| EMAC_MACFRMFILT | MAC Rx Frame Filter Register |
| EMAC_HASHTBL_HI | Hash Table High Register     |
| EMAC_HASHTBL_LO | Hash Table Low Register      |
| EMAC_SMI_ADDR   | SMI Address Register         |
| EMAC_SMI_DATA   | SMI Data Register            |
| EMAC_FLOWCTL    | FLOW Control Register        |
| EMAC_VLANTAG    | VLAN Tag Register            |
| EMAC_DBG        | Debug Register               |
| EMAC_ISTAT      | Interrupt Status Register    |
| EMAC_IMSK       | Interrupt Mask Register      |
| EMAC_ADDR0_HI   | MAC Address 0 High Register  |
| EMAC_ADDR0_LO   | MAC Address 0 Low Register   |
| EMAC_MMC_CTL    | MMC Control Register         |
| EMAC_MMC_RXINT  | MMC Rx Interrupt Register    |
| EMAC_MMC_TXINT  | MMC Tx Interrupt Register    |

**Table 23-1:** EMAC Module Registers (Continued)

| Name                | Description                                     |
|---------------------|-------------------------------------------------|
| EMAC_MMC_RXIMSK     | MMC Rx Interrupt Mask Register                  |
| EMAC_MMC_TXIMSK     | MMC TX Interrupt Mask Register                  |
| EMAC_TXOCTCNT_GB    | Tx OCT Count (Good/Bad) Register                |
| EMAC_TXFRMCNT_GB    | Tx Frame Count (Good/Bad) Register              |
| EMAC_TXBCASTFRM_G   | Tx Broadcast Frames (Good) Register             |
| EMAC_TXMCASTFRM_G   | Tx Multicast Frames (Good) Register             |
| EMAC_TX64_GB        | Tx 64-Byte Frames (Good/Bad) Register           |
| EMAC_TX65T0127_GB   | Tx 65- to 127-Byte Frames (Good/Bad) Register   |
| EMAC_TX128T0255_GB  | Tx 128- to 255-Byte Frames (Good/Bad) Register  |
| EMAC_TX256T0511_GB  | Tx 256- to 511-Byte Frames (Good/Bad) Register  |
| EMAC_TX512T01023_GB | Tx 512- to 1023-Byte Frames (Good/Bad) Register |
| EMAC_TX1024TOMAX_GB | Tx 1024- to Max-Byte Frames (Good/Bad) Register |
| EMAC_TXUCASTFRM_GB  | Tx Unicast Frames (Good/Bad) Register           |
| EMAC_TXMCASTFRM_GB  | Tx Multicast Frames (Good/Bad) Register         |
| EMAC_TXBCASTFRM_GB  | Tx Broadcast Frames (Good/Bad) Register         |
| EMAC_TXUNDR_ERR     | Tx Underflow Error Register                     |
| EMAC_TXSNGCOL_G     | Tx Single Collision (Good) Register             |
| EMAC_TXMULTCOL_G    | Tx Multiple Collision (Good) Register           |
| EMAC_TXDEFERRED     | Tx Deferred Register                            |
| EMAC_TXLATECOL      | Tx Late Collision Register                      |
| EMAC_TXEXCESSCOL    | Tx Excess Collision Register                    |
| EMAC_TXCARR_ERR     | Tx Carrier Error Register                       |

**Table 23-1:** EMAC Module Registers (Continued)

| Name                | Description                                     |
|---------------------|-------------------------------------------------|
| EMAC_TXOCTCNT_G     | Tx Octet Count (Good) Register                  |
| EMAC_TXFRMCNT_G     | Tx Frame Count (Good) Register                  |
| EMAC_TXEXCESSDEF    | Tx Excess Deferral Register                     |
| EMAC_TXPAUSEFRM     | Tx Pause Frame Register                         |
| EMAC_TXVLANFRM_G    | Tx VLAN Frames (Good) Register                  |
| EMAC_RXFRMCNT_GB    | Rx Frame Count (Good/Bad) Register              |
| EMAC_RXOCTCNT_GB    | Rx Octet Count (Good/Bad) Register              |
| EMAC_RXOCTCNT_G     | Rx Octet Count (Good) Register                  |
| EMAC_RXBCASTFRM_G   | Rx Broadcast Frames (Good) Register             |
| EMAC_RXMCASTFRM_G   | Rx Multicast Frames (Good) Register             |
| EMAC_RXCRC_ERR      | Rx CRC Error Register                           |
| EMAC_RXALIGN_ERR    | Rx alignment Error Register                     |
| EMAC_RXRUNT_ERR     | Rx Runt Error Register                          |
| EMAC_RXJAB_ERR      | Rx Jab Error Register                           |
| EMAC_RXUSIZE_G      | Rx Undersize (Good) Register                    |
| EMAC_RXOSIZE_G      | Rx Oversize (Good) Register                     |
| EMAC_RX64_GB        | Rx 64-Byte Frames (Good/Bad) Register           |
| EMAC_RX65T0127_GB   | Rx 65- to 127-Byte Frames (Good/Bad) Register   |
| EMAC_RX128T0255_GB  | Rx 128- to 255-Byte Frames (Good/Bad) Register  |
| EMAC_RX256T0511_GB  | Rx 256- to 511-Byte Frames (Good/Bad) Register  |
| EMAC_RX512T01023_GB | Rx 512- to 1023-Byte Frames (Good/Bad) Register |
| EMAC_RX1024TOMAX_GB | Rx 1024- to Max-Byte Frames (Good/Bad) Register |

**Table 23-1:** EMAC Module Registers (Continued)

| Name                    | Description                                    |
|-------------------------|------------------------------------------------|
| EMAC_RXUCASTFRM_G       | Rx Unicast Frames (Good) Register              |
| EMAC_RXLEN_ERR          | Rx Length Error Register                       |

| EMAC_TM_PPSWIDTH     | PPS Width Register                            |
| EMAC_DMA_BUSMODE     | DMA Bus Mode Register                         |
| EMAC_DMA_TXPOLL      | DMA Tx Poll Demand Register                   |
| EMAC_DMA_RXPOLL      | DMA Rx Poll Demand register                   |
| EMAC_DMA_RXDSC_ADDR  | DMA Rx Descriptor List Address Register       |
| EMAC_DMA_TXDSC_ADDR  | DMA Tx Descriptor List Address Register       |
| EMAC_DMA_STAT        | DMA Status Register                           |
| EMAC_DMA_OPMODE      | DMA Operation Mode Register                   |
| EMAC_DMA_IEN         | DMA Interrupt Enable Register                 |
| EMAC_DMA_MISS_FRM    | DMA Missed Frame Register                     |
| EMAC_DMA_RXIWDOG     | DMA Rx Interrupt Watch Dog Register           |
| EMAC_DMA_BMMODE      | DMA SCB Bus Mode Register                     |
| EMAC_DMA_BMSTAT      | DMA SCB Status Register                       |
| EMAC_DMA_TXDSC_CUR   | DMA Tx Descriptor Current Register            |

**Table 23-1:** EMAC Module Registers (Continued)

| Name               | Description                        |
|--------------------|------------------------------------|
| EMAC_DMA_RXDSC_CUR | DMA Rx Descriptor Current Register |
| EMAC_DMA_TXBUF_CUR | DMA Tx Buffer Current Register     |
| EMAC_DMA_RXBUF_CUR | DMA Rx Buffer Current Register     |

## ADSP-BF60x EMAC Interrupt List

**Table 23-2:** ADSP-BF60x EMAC Interrupt List

| Description  | ID | DMA Channel | Sensitivity |
|--------------|----|-------------|-------------|
| EMAC0 Status | 68 |             | LEVEL       |
| EMAC1 Status | 70 |             | LEVEL       |

## EMAC Definitions

The following definitions aid with using the EMAC.

### ***EMAC SCB***

System Crossbar interface of EMAC

### ***EMAC DMA***

DMA Controller of EMAC

### ***EMAC MFL***

MAC FIFO Layer inside EMAC

### ***EMAC CORE***

CORE Layer inside EMAC which does the actual Ethernet operations, including interface with PHY via RMII.

### ***MMC***

MAC Management Counter

### ***SMI***

Station Management Interface that controls PHY via MDIO/MDC signals.

### ***MII***

Reduced Media Independent Interface

### ***MAC***

Media Access Control

### ***PTP***

Precision Time Protocol

## EMAC Block Diagram and Interfaces

The below figure illustrates the overall functional architecture of the Ethernet MAC peripheral. The EMAC module basically comprises of four major layers, EMAC SCB, EMAC DMA, EMAC MFL and EMAC CORE. Each of these layers (sub-blocks) are explained in depth in their respective sections in this chapter.

**Figure 23-1:** EMAC Simplified Block Diagram

A more comprehensive block diagram is shown next, which includes most of the important blocks inside the EMAC. The EMAC is connected to processor memory and system crossbar via the System Crossbar Bus Interface (SCB) and System Peripheral Bus Interface (SPB), which are part of the SCB Layer. The SPB interface is connected to all modules that require MMR programming. The DMA controller performs application data transfer frame by frame, through well defined descriptor structures. A FIFO layer acts as a buffer between the DMA controller and the EMAC core. The EMAC core is the most important block as

it contains sub-blocks to support IEEE802.3 based communication with external network interfaces of 10/100 Mbps speeds. It includes the PTP sub-block to assist applications requiring time synchronization and a MMC sub-block to generate packet transfer statistics. The MAC is connected to the external PHY via the Reduced Media Independent Interface (RMII) and the Station Management Interface (Serial Management IO).

Figure 23-2: EMAC Complete Block Diagram

EMAC CORE Sub-blocks

The core transmit engine sub-blocks and their function are summarized in the below table. Please refer to the EMAC core section for further explanation of each of these sub-blocks.

Table 23-3: Core Transmit Engine sub-blocks

| CORE Transmit Engine Sub Block | Function               |
|--------------------------------|------------------------|
| Transmit Bus Interface         | Interface to the FIFO. |

**Table 23-3:** Core Transmit Engine sub-blocks (Continued)

| CORE Transmit Engine Sub Block   | Function                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Transmit Frame Controller        | <ul style="list-style-type: none"> <li>–Appends Zero-PAD data if required, for short frames.</li> <li>–Appends CRC for Frame Check-Sum from the CRC Generator.</li> </ul>                                                                                                                                                                  |
| Transmit Protocol Engine         | <ul style="list-style-type: none"> <li>–Generates preamble and SFD, as per 802.3 protocol.</li> <li>–Generates jam pattern in Half-Duplex mode, for collisions.</li> <li>–Jabber timeout, for excessively large frames.</li> <li>–Flow control for Half-Duplex mode (back pressure).</li> <li>–Generates transmit frame status.</li> </ul> |
| Transmit Scheduler               | <ul style="list-style-type: none"> <li>–Maintains the inter-frame gap between two transmitted frames.</li> <li>–Follows the Truncated Binary Exponential Back-off algorithm for Half-Duplex mode.</li> </ul>                                                                                                                               |
| Transmit CRC Generator           | Generate CRC for the Frame Check-Sum field of the Ethernet frame.                                                                                                                                                                                                                                                                          |
| Transmit Flow Control            | Receives the Pause frame, appends the calculated CRC, and sends the frame to the Protocol Engine module.                                                                                                                                                                                                                                   |
| Transmit Checksum Offload Engine | Supports checksum calculation and insertion in the transmit path, for IPV4/TCP/UDP/ICMP packets.                                                                                                                                                                                                                                           |

The core receive engine sub-blocks and their function are summarized in the following table. Please refer to the EMAC core section for more information on each of these sub-blocks.

**Table 23-4:** Core Receive Engine sub-blocks

| CORE Receive Engine sub block | Functionality overview                                                                                                                                                                                                                                                                                          |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Receive Protocol Engine       | <ul style="list-style-type: none"> <li>–Strips the incoming preamble and SFD.</li> <li>–Checks for correct Length/Type field.</li> <li>–Performs internal loopback if required.</li> <li>–Generates receive status.</li> <li>–Supports watchdog of received frames.</li> <li>–Supports Jumbo Frames.</li> </ul> |
| Receive CRC Module            | Checks for CRC error, by comparing with FCS.                                                                                                                                                                                                                                                                    |

**Table 23-4:** Core Receive Engine sub-blocks (Continued)

| CORE Receive Engine sub block      | Functionality overview                                                                                                                                                                                                                                                                                                                 |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Receive Frame Controller Module    | <ul style="list-style-type: none"> <li>–Packs incoming 8-bit input stream to 32-bit data internally.</li> <li>–Performs Frame filtering, for uni-cast/multi-cast/broadcast frames.</li> <li>–Attaches the calculated IP Checksum input from Checksum Offload Engine.</li> <li>–Updates the Receive Status to Bus Interface.</li> </ul> |
| Receive Flow Control Module        | <ul style="list-style-type: none"> <li>–Detects the receiving Pause frame and pauses the frame transmission for the delay specified within the received Pause frame.</li> <li>–Works in Full Duplex mode.</li> </ul>                                                                                                                   |
| Receive IP Checksum Offload Engine | <ul style="list-style-type: none"> <li>–Calculates IPv4 header checksums and verify against the received IPv4 header checksums.</li> <li>–Identifies a TCP, UDP or ICMP payload in the received IP datagrams.</li> </ul>                                                                                                               |
| Receive Bus Interface Unit Module  | Interface to the FIFO.                                                                                                                                                                                                                                                                                                                 |
| Address Filtering Module           | <p>Performs Destination Address Filtering based on Unicast/ Multi-cast/Broadcast frames.</p> <ul style="list-style-type: none"> <li>–Provides CRC hash filtering.</li> </ul>                                                                                                                                                           |

## PHY Interface

The EMAC can be interfaced to the PHY via the RMII interface standard. The tables below indicate the RMII pins available in the EMAC in terms of their generic names. Please refer to the data sheet for exact pin names.

**Table 23-5:** RMII pins

| Sl. No. | Generic Signal Name (IEEE Standards) | RMII Pin functionality.                   |
|---------|--------------------------------------|-------------------------------------------|
| 1.      | TXD0                                 | RMII transmit data pin D0 (di-bit lower)  |
| 2.      | TXD1                                 | RMII transmit data pin D1 (di-bit higher) |
| 3.      | RXD0                                 | RMII receive data pin D0 (di-bit lower)   |

**Table 23-5:** RMII pins (Continued)

| Sl. No. | Generic Signal Name (IEEE Standards) | RMII Pin functionality.                                        |
|---------|--------------------------------------|----------------------------------------------------------------|
| 4.      | RXD1                                 | RMII receive data pin D1 (di-bit higher)                       |
| 5.      | RMII CLK                             | RMII common clock (for Tx and Rx), also called reference clock |
| 6.      | TXEN                                 | RMII transmit enable pin (Tx valid)                            |
| 7.      | CRS                                  | RMII Carrier Sense / receive data valid                        |
| 8.      | MDC                                  | Serial management clock driven by EMAC                         |
| 9.      | MDIO                                 | Serial management bi-directional data                          |

**Figure 23-3:** RMII di-bit data transfer

## EMAC Clock Sources

The Ethernet MAC is clocked internally from SCLK. Check the processor data sheet for the valid frequency range of the appropriate SCLK signal for Ethernet operation.

A 50 MHz clock should be sourced externally to operate the EMAC in RMII mode. This clock is same for both transmission and reception. The MDC Station Management Clock is derived from the SCLK and driven from the MAC to the PHY, when accessing any PHY registers.

**Figure 23-4:** EMAC Clock Sources

## EMAC Architectural Concepts

This section explains different architectural concepts relevant to EMAC peripheral, such as EMAC SCB, EMAC DMA EMAC MFL, EMAC CORE and others.

### EMAC System Crossbar Interface (EMAC SCB)

The EMAC SCB bus interface provides the bus connectivity to support highly effective data traffic throughput. The system bus use is maximized by allowing simultaneous read and write transfers initiated from different DMA channels. The EMAC controller is directly hooked up to the SCB0 crossbar of BF60x. the following interfaces are available with the design:

- A 32 bit SCB master interface for reading/writing from/to application memory.
- A 32 bit SPB slave interface for register programming.

Please refer to the System Crossbars (SCB) chapter for more information on how the crossbar operates. Only the EMAC specific information is detailed in this chapter.

**Table 23-6:** EMAC-SCB Interface Data Transfer Specifications with Crossbar

| Specification Term | Comments                             |
|--------------------|--------------------------------------|
| 1 beat in SCB      | SINGLE burst                         |
| BLEN4 bursts       | 4 beats in SCB                       |
| BLEN8 bursts       | 8 beats in SCB                       |
| BLEN16 bursts      | 16 beats in SCB                      |
| Bus size           | 32-bit fixed bus size; equals 1 beat |
| INCR bursts        | Incrementing Bursts                  |

**Table 23-6:** EMAC-SCB Interface Data Transfer Specifications with Crossbar (Continued)

| Specification Term  | Comments                          |
|---------------------|-----------------------------------|
| INCR ALIGNED bursts | Incrementing aligned bursts       |
| UNDEF bursts        | Undefined burst length            |
| PBL                 | Programmable Burst Length for DMA |

DMA Write Channel and Read Channel data paths with the system crossbar is shown below.

**Figure 23-5:** EMAC DMA Read/Write channels with System Crossbar

**NOTE:** Transmit descriptor read and receive descriptor write-back (status update) operation can occur simultaneously. However transmit descriptor read and transmit descriptor write-back operation cannot occur simultaneously as transmit DMA (or receive DMA) does not initiate the next transfer unless the previous one is complete.

### Priority of SCB Requests

The Descriptor transfers have higher priority than the data transfers. So, if there are two bus requests, for example, receive descriptor read and transmit data read, then receive descriptor read is given higher priority so, that the next receive data write (subsequent to receive descriptor read) need not wait for transmit data read transfer to complete. If there are descriptor read requests from both DMA channels, then they are serviced based on a first-come first-serve basis. Receive DMA has higher priority if descriptor read requests are generated from both the DMAs in the same clock. Similarly, in the write channel, descriptor writes from any DMA have higher priority than the data-write transfers for the Receive DMA.

## SCB Interface Programming Options

The SCB bus interface supports the following options for the EMAC module. The `DMA_BMMODE` register together with the `DMA_BUSMODE` register controls the programmable features of the SCB master interface.

- **Outstanding Transactions:** The EMAC-SCB supports up to four Read/Write outstanding requests on the SCB bus. This can also be controlled through software by programming the `WROSRLMT`/`RDOSRLMT` bits in the DMA Bus Mode Register. Maximum outstanding requests = `WROSRLMT` + 1 (or) `RDOSRLMT` + 1.
- **Allowed burst sizes:** 4 (`BLLEN4`), 8 (`BLLEN8`), 16 (`BLLEN16`) and the `SINGLE` burst. Only those burst sizes configured by user (via `DMA_BMMODE` register) are used for data transfer through the SCB bus. However, `SINGLE` burst is available by default, when the `UNDEF` bit in the `DMA_BMMODE` register is cleared. Data transfers are restricted to the maximum burst size from this list of programmed burst sizes.
- **Burst Splitting and Burst Selection:** The EMAC-SCB splits the DMA requests into multiple bursts on the SCB System Bus. The splitting is based on DMA count and software controllable burst enable bits `UNDEF`, `BLLEN16`, `BLLEN8`, and `BLLEN4` as well as burst types (`INCR` and `INCR_ALIGNED`) which are also controllable through the software. `SINGLE` burst is enabled when the `UNDEF` bit is not set. Burst length select priority is in the sequence: `UNDEF`, `BLLEN16`, `BLLEN8`, and `BLLEN4`.
- **INCR Burst Type:**
  - If the `UNDEF` bit in `DMA_BMMODE` register is set, then EMAC-SCB always chooses the maximum allowed burst length based on the `BLLEN16`, `BLLEN8`, `BLLEN4` bits. In cases where the DMA requests are not multiples of the maximum allowed burst length, the SCB may also choose a burst-length of any value less than the maximum enabled burst-length (all lesser burst-length enables are redundant). For example, when `BLLEN16`, `BLLEN8`, `BLLEN4` are enabled and the DMA requests a burst transfer size of 42 beats, then the SCB splits it into three bursts of 16, 16 and 10 beats respectively.
  - If `UNDEF` is not enabled, then the burst length is based on the priority of the enabled bits in the following order (`BLLEN16`, `BLLEN8`, and `BLLEN4`). When the DMA requests a burst transfer, the SCB interface splits the requested bursts into multiple transfers using only the enabled burst lengths. This splitting can occur when the requested burst is not a multiple of the maximum enabled burst. If it cannot choose any of the enabled burst lengths then it selects the burst length as 1. For example, when `BLLEN16`, `BLLEN8`, `BLLEN4` are enabled and the DMA requests a burst transfer of 42 beats, then the SCB interface splits it into multiple bursts of size 16, 16, 8, 1 and 1 beats respectively (the sequence is in decreasing burst sizes).
- **INCR\_ALIGNED Burst Type:** When the address-aligned burst-type is enabled (`AAL` bit in `DMA_BMMODE` register), then in addition to the burst splitting conditions explained in the `INCR` Burst type, the SCB interface splits the DMA requested bursts such that each burst-size is aligned to the least significant bits of the start address. The SCB interface initially generates smaller bursts so that the remaining transfers can be transferred with the maximum possible (enabled) fixed burst lengths. For example, in the same setting as explained earlier for `UNDEF` set (`BLLEN16`, `BLLEN8` and `BLLEN4` are enabled), DMA requests a burst size of 42 beats at the start address of `0x000003A4`. The SCB starts the first transfer with size 3 such that the address of the next burst is aligned (`0x000003B0`) for a burst of 16. Therefore, the sequence of bursts would be 3, 16, 16, and 7, respectively. When `UNDEF` is not set, then in the same scenario (start address

of 0x000003A4 with 42 beats), the sequence of burst transfers would be 1, 1, 1, 16, 16, 4, and 3 respectively. The sequence of smaller bursts at the beginning is to align the address to the next higher enabled burst-lengths programmed in the register.

- Burst operations for DMA transactions: PBL (Programmable Burst Length) field of the DMA\_BUSMODE [13:8] register indicate the maximum number of beats to be transferred in one DMA transaction. This is also the maximum value that is used in a single block read/write.

**Table 23-7:** DMA PBL Max Limits

| Burst Limit max term     | Definition                    |
|--------------------------|-------------------------------|
| PBL-max limit            | (FIFO size / 2) / 4 words.    |
| PBL-max limit (transmit) | 256 bytes / 2 / 4 = 32 words. |
| PBL-max limit (receive)  | 128 bytes / 2 / 4 = 16 words. |

- For example, if PBL = 32 and if BLEN16 is enabled, the DMA automatically splits 32 bursts in to 2 x 16 bursts. If PBL = 8, and if BLEN16 and BLEN8 are enabled, the maximum burst is limited to BLEN8. If the PBL8 bit in the DMA\_BUSMODE register is set, the programmed PBL value is multiplied by 8 times internally. However, the result cannot be more than the maximum limits specified above.
- The Receive DMA burst length configuration can be made independent of transmit DMA configuration, by setting the bit in the register. If this bit is set, bits defines the burst length of receive DMA. If bit is not set, the bits are used for both transmit and receive. Programs must ensure that the PBL maximum limit is not violated.
- The Receive and Transmit descriptors are always accessed in the maximum possible burst-size (limited by PBL maximum for transmit and receive) for the 16-bytes to be read.

## DMA Bursts with SCB Interface

The Transmit DMA initiates a data transfer only when sufficient space to accommodate the configured burst is available in the Transmit FIFO or the number of bytes until the end of frame (when it is less than the configured burst-length). The DMA indicates the start address and the number of transfers required to the SCB master interface. When the SCB interface is configured for fixed-length burst, then it transfers data using the best combination of INCR4/8/16 and 1 beat transaction.

The Receive DMA initiates a data transfer only when sufficient data to accommodate the configured burst is available in the MTL Receive FIFO or when the end of frame (when it is less than the configured burst-length) is detected in the Receive FIFO. The DMA indicates the start address and the number of transfers required to the SCB master interface. When the SCB interface is configured for fixed-length burst, then it transfers data using the best combination of INCR 4/8/16 or 1 beat transaction. If the end-of frame is reached before the fixed-burst ends on the SCB interface, then dummy transfers are performed in-order to complete the fixed-burst. Otherwise (if DMA\_BUSMODE.FB is reset), it transfers data using INCR (undefined length) transactions.

When the SCB interface is configured for address-aligned beats (AAL), both DMA engines ensure that the first burst transfer the SCB initiates is less than or equal to the size of the configured PBL. Thus, all subsequent beats start at an address that is aligned to the configured PBL.

## SCB Bus Transaction Status

The `BUSRD` and `BUSWR` bits of the `DMA_BMSTAT` register give the status of SCB bus activities. These bits indicate whether the channel is active or not.

## Fatal Bus Error

The EMAC SCB asserts the error interrupt when the corresponding Fatal Bus Error interrupt is enabled in the DMA interrupt enable register. The application has to reset the core to restart the DMA.

## EMAC DMA Controller (EMAC DMA)

The EMAC has an in-built DMA controller that performs reads and writes of application data and descriptors via the SCB master interface.

The DMA has independent transmit and receive engines, and a CSR (control and status register) space. The transmit engine transfers data from system memory to a FIFO, while the receive engine transfers data from the FIFO to the system memory. The controller uses a descriptor chain based transfer mechanism to efficiently move data from source to destination with minimal processor core intervention. The DMA is specially designed for packet-oriented data transfers such as Ethernet frames. The controller can be programmed to interrupt the application for situations such as frame transmit and receive transfer completion, and other normal or abnormal conditions.

The DMA and the application device driver communicate through two internal data structures:

1. DMA Control and Status registers (CSR).
2. Descriptor lists and data buffers.

Descriptors that reside in the application memory act as pointers to receive and transmit buffers. There are two descriptor lists, one for receive, and one for transmit. The base address of each list is written into the receive descriptor list address register and transmit descriptor list address register, respectively. A descriptor list is forward linked (either implicitly or explicitly). The last descriptor may point back to the first entry to create a ring structure. Explicit chaining of descriptors is accomplished by setting the second address chained in both receive and transmit descriptors. The descriptor lists reside in the application memory address space. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers may contain only data and buffer status is maintained in the descriptor itself. Data chaining refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA will skip to the next frame buffer when the end-of-frame is detected. Data chaining can be enabled or disabled.

As mentioned above, the controller supports two types of descriptors: ring mode and chain mode. Their functional structure as provided to the user is shown in below figures.

**Figure 23-6:** EMAC DMA Descriptor Models

**NOTE:** It is possible to define a skip length (in terms of  $N \times 32$ -bit words) between two subsequent descriptors, when using ring mode. The DSL field in the DMA bus mode register must be programmed to enable this. With this option available, programs are not always restricted to a contiguous memory location in ring mode.

## DMA Related Registers

A summary of DMA registers relative to their functionality is given below. Please refer to the Register Descriptions sections for complete bit descriptions of each of these registers.

**Table 23-8:** Summary of DMA related Registers.

| Register Name     | Related Functionality                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------------|
| Bus Mode Register | The Bus Mode Register establishes the bus operating modes for the DMA with respect to the SCB master interface. |

**Table 23-8:** Summary of DMA related Registers. (Continued)

| Register Name                                     | Related Functionality                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Transmit Poll Demand Register                     | The Transmit Poll Demand Register enables the transmit DMA to check whether or not the current descriptor is owned by DMA. The Transmit Poll Demand command is given to wake up the TxDMA if it is in Suspend mode. The TxDMA can go into suspend mode because of an Underflow error in a transmitted frame or because of the unavailability of descriptors owned by transmit DMA. You can give this command anytime and the TxDMA resets this command once it starts re-fetching the current descriptor from host memory. |
| Receive Poll Demand Register                      | The Receive Poll Demand Register enables the receive DMA to check for new descriptors. This command is given to wake up the RxDMA from SUSPEND state. The RxDMA can go into SUSPEND state only because of the unavailability of descriptors owned by it.                                                                                                                                                                                                                                                                   |
| Receive Descriptor List Address Register          | The Receive Descriptor List Address Register points to the start of the Receive Descriptor List. The descriptor lists reside in the application memory space and must be Word -aligned (32- bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low.                                                                                                                                                                                                            |
| Transmit Descriptor List Address Register         | The Transmit Descriptor List Address Register points to the start of the Transmit Descriptor List. The descriptor lists reside in the application memory space and must be Word (for 32-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.                                                                                                                                                                                                                 |
| DMA Status Register                               | The Status Register contains all the status bits that the DMA reports to the application. The Software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted.                                                                                                                                                                                                                                                                    |
| Operation Mode Register                           | The Operation Mode Register establishes the Transmit and Receive operating modes and commands. Operation Mode Register should be the last Control Register to be written as part of DMA initialization.                                                                                                                                                                                                                                                                                                                    |
| Interrupt Enable Register                         | The Interrupt Enable Register enables the interrupts reported by DMA Status Register. After a hardware or software reset, all interrupts are disabled.                                                                                                                                                                                                                                                                                                                                                                     |
| Missed Frame and Buffer Overflow Counter Register | The DMA maintains two counters to track the number of missed frames during reception. This Register reports the current value of the counter, which is used for diagnostic purposes.                                                                                                                                                                                                                                                                                                                                       |

**Table 23-8:** Summary of DMA related Registers. (Continued)

| Register Name                                 | Related Functionality                                                                                                                                          |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Receive Interrupt Watchdog Timer Register     | This register, when written with non-zero value, enables the watchdog timer for Receive Interrupt (RI) in DMA Status Register.                                 |
| SCB Bus Mode Register                         | The SCB Bus Mode Register controls the SCB interface master behavior. It is mainly used to control the burst splitting and the number of outstanding requests. |
| SCB Status Register                           | The active status of the SCB interface read & write channels are given in this Register.                                                                       |
| Current Host Transmit Descriptor Register     | The Current Host Transmit Descriptor Register points to the start address of the current Transmit Descriptor read by the DMA.                                  |
| Current Host Receive Descriptor Register      | The Current Host Receive Descriptor Register points to the start address of the current Receive Descriptor read by the DMA.                                    |
| Current Host Transmit Buffer Address Register | The Current Host Transmit Buffer Address Register points to the current Transmit Buffer Address being read by the DMA.                                         |
| Current Host Receive Buffer Address Register  | The Current Host Receive Buffer Address Register points to the current Receive Buffer address being read by the DMA.                                           |

**NOTE:** There should not be any further writes to the below registers until the first write is updated. Otherwise, the second write operation will not get updated properly. For correct operation, the delay between two writes to the same register location should be at least 8 cycles of 50 MHz RMII REFCLK.

**Table 23-9:** DMA Registers with Consecutive Writes

| Registers with Implications for Consecutive Writes |
|----------------------------------------------------|
| DMA Bus Mode Register                              |

## DMA Descriptors

The DMA module in the Ethernet subsystem transfers data based on a linked list of descriptors. The descriptor addresses must be aligned to the 32-bit bus width. The descriptors can be either 4 x 32-bit words (16 bytes) or 8 x 32-bit words (32 bytes). The controller needs to be configured for the appropriate WORD length using the DMA Bus Mode Register. Descriptor words are numbered from 0 to 7 for both transmit and receive engine.

Typical factors for deciding the descriptor word size:

1. When Time-stamping or receive checksum engine are not enabled, the extended descriptors are not required and the software can use descriptors with the default size of 16 bytes (4 words).
2. When Time-stamping feature is enabled (to be used with the IEEE 1588 PTP Engine), the software needs to allocate 32-bytes (8 words) of memory for every descriptor.
3. When only the receive checksum off-load is enabled (time stamping disabled) the software needs to allocate 32-bytes (8 words) of memory for every descriptor, although in reality only word 4 of the extended words (descriptors 4–7) contain the required status information. The rest of extended words may be treated as reserved or dummy.

## Transmit Descriptor

The transmit descriptor structure is shown in the below figure. The application software must program the TDES0 control bits during descriptor initialization. When the DMA updates the descriptor, it write backs all the control bits except the `OWN` bit (which it clears) and updates the status bits. The contents of the transmitter descriptor word 0 (TDES0) through word 7 (TDES7) are given in the following tables.

**Figure 23-7:** Transmit Descriptor words

**Table 23-10:** Transmit Descriptor Fields (TDES0)

| Bit | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31  | OWN  | Own Bit. When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the application. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are read completely. The ownership bit of the frame's first descriptor must be set after all subsequent descriptors belonging to the same frame have been set. This avoids a possible race condition between fetching a descriptor and the driver setting an ownership bit. |
| 30  | IC   | Interrupt on Completion. When set, this bit sets the transmit interrupt (DMA status register [0]) after the present frame has been transmitted.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 29  | LS   | Last Segment. When set, this bit indicates that the buffer contains the last segment of the frame                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 28  | FS   | First Segment. When set, this bit indicates that the buffer contains the first segment of a frame.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 27  | DC   | Disable CRC. When this bit is set, the EMAC does not append a cyclic redundancy check (CRC) to the end of the transmitted frame. This is valid only when the first segment (TDES0[28]) is set.                                                                                                                                                                                                                                                                                                                                                                           |
| 26  | DP   | Disable Pad. When set, the EMAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes, and the CRC field is added despite the state of the DC (TDES0[27]) bit. This is valid only when the first segment (TDES0[28]) is set.                                                                                                                                                                                                                          |
| 25  | TTSE | Transmit Time Stamp Enable. When set, this bit enables IEEE1588 hardware time stamping for the transmit frame referenced by the descriptor. This field is valid only when the First Segment control bit (TDES0[28]) is set.                                                                                                                                                                                                                                                                                                                                              |
| 24  |      | Reserved                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 23-10:** Transmit Descriptor Fields (TDES0) (Continued)

| Bit   | Name     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 23:22 | CIC      | Checksum Insertion Control. These bits control the checksum calculation and insertion. Bit encodings are as shown below.<br>2'b00 = Checksum Insertion Disabled.<br>2'b01 = Only IP header checksum calculation and insertion are enabled.<br>2'b10 = IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware.<br>2'b11 = IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware.                                                                                                 |
| 21    | TER      | Transmit End of Ring. When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 20    | TCH      | Second Address Chained. When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When TDES0[20] is set, TBS2 (TDES1[28:16]) is a <i>don't care</i> value. TDES0[21] takes precedence over TDES0[20].                                                                                                                                                                                                                                                                                                                                                       |
| 19:18 | Reserved |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 17    | TTSS     | Transmit Time Stamp Status. This field is used as a status bit to indicate that a time stamp was captured for the described transmit frame. When this bit is set, TDES2 and TDES3 have a time stamp value captured for the transmit frame. This field is only valid when the descriptor's Last Segment control bit (TDES0[29]) is set.                                                                                                                                                                                                                                                                                                         |
| 16    | IHE      | IP Header Error. When set, this bit indicates that the EMAC transmitter detected an error in the IP datagram header. The transmitter checks the header length in the IPv4 packet against the number of header bytes received from the application and indicates an error status if there is a mismatch. For IPv6 frames, a header error is reported if the main header length is not 40 bytes. Furthermore, the Ethernet Length/Type field value for an IPv4 or IPv6 frame must match the IP header version received with the packet. For IPv4 frames, an error status is also indicated if the Header Length field has a value less than 0x5. |

**Table 23-10:** Transmit Descriptor Fields (TDES0) (Continued)

| Bit | Name | Description                                                                                                                                                                                                                                                                                                                                                                   |
|-----|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15  | ES   | Error Summary. Indicates the logical OR of the following bits.<br>TDES0[14] = Jabber Timeout<br>TDES0[13] = Frame Flush<br>TDES0[11] = Loss of Carrier<br>TDES0[10] = No Carrier<br>TDES0[9] = Late Collision<br>TDES0[8] = Excessive Collision<br>TDES0[2] = Excessive Deferral<br>TDES0[1] = Underflow Error<br>TDES0[16] = IP Header Error<br>TDES0[12] = IP Payload Error |
| 14  | JT   | Jabber Timeout. When set, this bit indicates the EMAC transmitter has experienced a jabber time-out. This bit is only set when the EMAC configuration register's JD bit is not set.                                                                                                                                                                                           |
| 13  | FF   | Frame Flushed. When set, this bit indicates that the DMA/MFL flushed the frame due to a software Flush command given by the CPU.                                                                                                                                                                                                                                              |
| 12  | IPE  | IP Payload Error. When set, this bit indicates that EMAC transmitter detected an error in the TCP, UDP, or ICMP IP datagram payload. The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP, or ICMP packet bytes received from the application and issues an error status in case of a mismatch.                |
| 11  | LC   | Loss of Carrier. When set, this bit indicates that a loss of carrier occurred during frame transmission. This is valid only for the frames transmitted without collision when the EMAC operates in Half-Duplex mode.                                                                                                                                                          |
| 10  | NC   | No Carrier. When set, this bit indicates that the Carrier Sense signal from the PHY was not asserted during transmission.                                                                                                                                                                                                                                                     |
| 9   | LC   | Late Collision. When set, this bit indicates that frame transmission was aborted due to a collision occurring after the collision window (64 byte-times, including preamble). This bit is not valid if the Underflow Error bit is set.                                                                                                                                        |
| 8   | EC   | Excessive Collision. When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If the DR (Disable Retry) bit in the EMAC Configuration register is set, this bit is set after the first collision, and the transmission of the frame is aborted.                                          |

**Table 23-10:** Transmit Descriptor Fields (TDES0) (Continued)

| Bit | Name             | Description                                                                                                                                                                                                                                                                                                                                                                                 |
|-----|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | VF               | VLAN Frame. When set, this bit indicates that the transmitted frame was a VLAN-type frame.                                                                                                                                                                                                                                                                                                  |
| 6:3 | CC               | Collision Count. This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the Excessive Collisions bit (TDES0[8]) is set.                                                                                                                                                                                        |
| 2   | ED               | Excessive Deferral? When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1,000-Mbps mode or if Jumbo Frame is enabled) if the Deferral Check (DC) bit in the EMAC Control register is set high.                                                                                                       |
| 1   | UF               | Underflow Error. When set, this bit indicates that the EMAC aborted the frame because data arrived late from the application memory. Underflow Error indicates that the DMA encountered an empty transmit buffer while transmitting the frame. The transmission process enters the Suspended state and sets both Transmit Underflow (Register 5[5]) and Transmit Interrupt (Register 5[0]). |
| 0   | DB: Deferred Bit | When set, this bit indicates that the EMAC defers before transmission because of the presence of carrier. This bit is valid only in Half-Duplex mode.                                                                                                                                                                                                                                       |

**Table 23-11:** Transmit Descriptor Word 1 (TDES1)

| Bit   | Name     | Description                                                                                                                                                                                                                 |
|-------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–29 | Reserved |                                                                                                                                                                                                                             |
| 28–16 | TBS2     | Transmit Buffer 2 Size. These bits indicate the second data buffer size in bytes. This field is not valid if TDES0[20] is set.                                                                                              |
| 15–13 | Reserved |                                                                                                                                                                                                                             |
| 12–0  | TBS1     | Transmit Buffer 1 Size. These bits indicate the first data buffer byte size, in bytes. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor, depending on the value of TCH (TDES0[20]). |

**Table 23-12:** Transmit Descriptor 2 (TDES2)

| Bit  | Name                     | Description                                                                                                  |
|------|--------------------------|--------------------------------------------------------------------------------------------------------------|
| 31–0 | Buffer 1 Address Pointer | These bits indicate the physical address of buffer 1. There is no limitation on the buffer address alignment |

**Table 23-13:** Transmit Descriptor 3 (TDES3)

| Bit  | Name                                               | Description                                                                                                                                                                                                                                                                                                                                                      |
|------|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–0 | Buffer 2 Address Pointer (Next Descriptor Address) | Indicates the physical address of buffer 2 when a descriptor ring structure is used. If the second address chained (TDES1[24]) bit is set, this address contains the pointer to the physical memory where the next descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES1[24] is set. (LSBs are ignored internally.) |

**Table 23-14:** Transmit Descriptor 6 (TDES6)

| Bit  | Name | Description                                                                                                                                                                                                                                                                                       |
|------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–0 | TTSL | Transmit Frame Time Stamp Low. This field is updated by DMA with the least significant 32 bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the Last Segment bit (LS) in the descriptor is set and Time stamp status (TTSS) bit is set. |

**Table 23-15:** Transmit Descriptor 7 (TDES7)

| Bit  | Name | Description                                                                                                                                                                                                                                                                                      |
|------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–0 | TTSH | Transmit Frame Time Stamp High. This field is updated by DMA with the most significant 32 bits of the time stamp captured for the corresponding receive frame. This field has the time stamp only if the Last Segment bit (LS) in the descriptor is set and Time stamp status (TTSS) bit is set. |

## Receive Descriptor

The structure of the receive descriptor is shown below. This can have 32 bytes of descriptor data (8 DWORDs) when advanced time stamping or checksum is enabled.

Figure 23-8: Receive Descriptor words

Table 23-16: Receive Descriptor Fields (RDES0)

| Bit   | Name | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | OWN  | Own. When set, this bit indicates that the descriptor is owned by the DMA of the EMAC Subsystem. When this bit is reset, this bit indicates that the descriptor is owned by the application. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.                                                                                                                                                                     |
| 30    | AFM  | Destination Address Filter Fail. When set, this bit indicates a frame that failed in the DA Filter in the EMAC CORE.                                                                                                                                                                                                                                                                                                                                                                                         |
| 29–16 | FL   | Frame Length. These bits indicate the byte length of the received frame that was transferred to application memory (including CRC). This field is valid when last descriptor (RDES0[8]) is set and either the descriptor error (RDES0[14]) or overflow error bits are reset. This field is valid when Last Descriptor (RDES0[8]) is set. When the last descriptor and error summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current frame. |

**Table 23-16:** Receive Descriptor Fields (RDES0) (Continued)

| Bit | Name                 | Description                                                                                                                                                                                                                                                                                                                                              |
|-----|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15  | ES                   | Error Summary. Indicates the logical OR of the following bits.<br>RDES0[1] = CRC Error<br>RDES0[4] = Watchdog Timeout<br>RDES0[6] = Late Collision<br>RDES0[7] = Giant Frame<br>RDES0[4:3] = IP Header/Payload Error<br>RDES0[11] = Overflow Error<br>RDES0[14] = Descriptor Error. This field is valid only when the last descriptor (RDES0[8]) is set. |
| 14  | DE                   | Descriptor Error. When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the next descriptor. The frame is truncated. This field is valid only when the Last Descriptor (RDES0[8]) is set.                                                             |
| 13  | Reserved             |                                                                                                                                                                                                                                                                                                                                                          |
| 12  | LE                   | Length Error. When set, this bit indicates that the actual length of the frame received and that the Length/ Type field does not match. This bit is valid only when the Frame Type (RDES0[5]) bit is reset.                                                                                                                                              |
| 11  | OE                   | Overflow Error. When set, this bit indicates that the received frame was damaged due to buffer overflow in MFL.                                                                                                                                                                                                                                          |
| 10  | VLAN                 | VLAN Tag. When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the EMAC CORE.                                                                                                                                                                                                                             |
| 9   | FS                   | First Descriptor. When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next Descriptor contains the beginning of the frame.                                            |
| 8   | LS                   | Last Descriptor. When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame                                                                                                                                                                                                                           |
| 7   | Time Stamp Available | When set, this bit indicates that a snapshot of the timestamp is written in descriptor words 6 (RDES6) and 7 (RDES7). This is valid only when the Last Descriptor bit (RDES0[8]) is set                                                                                                                                                                  |
| 6   | LC                   | Late Collision. When set, this bit indicates that a late collision has occurred while receiving the frame in Half-Duplex mode.                                                                                                                                                                                                                           |

**Table 23-16:** Receive Descriptor Fields (RDES0) (Continued)

| Bit | Name                      | Description                                                                                                                                                                                                                                                                                  |
|-----|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5   | FT                        | Frame Type. When set, this bit indicates that the Receive Frame is an Ethernet-type frame (the LT field is greater than or equal to 16'h0600). When this bit is reset, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames less than 14 bytes. |
| 4   | RWT                       | Receive Watchdog Timeout. When set, this bit indicates that the Receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout.                                                                                          |
| 3   | Reserved                  |                                                                                                                                                                                                                                                                                              |
| 2   | DE                        | Dribble Bit Error. When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles).                                                                                                                                                                   |
| 1   | CE                        | CRC Error. When set, this bit indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received frame. This field is valid only when the Last Descriptor (RDES0[8]) is set.                                                                                                      |
| 0   | Extended Status Available | When set, this bit indicates that the extended status is available in descriptor word 4 (RDES4). This is valid only when the Last Descriptor bit (RDES0[8]) is set.                                                                                                                          |

**Table 23-17:** Receive Descriptor Fields 1 (RDES1)

| Bit   | Name     | Description                                                                                                                                                                                                                                                                                                                                                                    |
|-------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | DIC      | Disable Interrupt on Completion. When set, this bit prevents setting the status register's RI bit (DMA status register [6]) for the received frame ending in the buffer indicated by this descriptor. This, in turn, disables the assertion of the interrupt to Application due to RI for that frame.                                                                          |
| 30–29 | Reserved |                                                                                                                                                                                                                                                                                                                                                                                |
| 28–16 | RBS2     | Receive Buffer 2 Size. These bits indicate the second data buffer size, in bytes. The buffer size must be a multiple of 4, (32-bit bus), even if the value of RDES3 (buffer2 address pointer) is not aligned to bus width. If the buffer size is not an appropriate multiple of 4, 8, or 16, the resulting behavior is undefined. This field is not valid if RDES1[14] is set. |
| 15    | RER      | Receive End of Ring. When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.                                                                                                                                                                                          |

**Table 23-17:** Receive Descriptor Fields 1 (RDES1) (Continued)

| Bit  | Name     | Description                                                                                                                                                                                                                                                                                                                                                                                                    |
|------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14   | RCH      | Second Address Chained. When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When this bit is set, RBS2 (RDES1[28:16]) is a <i>don't care</i> value. RDES1[15] takes precedence over RDES1[14].                                                                                                                        |
| 13   | Reserved |                                                                                                                                                                                                                                                                                                                                                                                                                |
| 12–0 | RBS1     | Receive Buffer 1 Size. Indicates the first data buffer size in bytes. The buffer size must be a multiple of 4 (32-bit bus), even if the value of RDES2 (buffer1 address pointer) is not aligned. When the buffer size is not a multiple of 4 the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of RCH (Bit 14). |

**Table 23-18:** Receive Descriptor Fields 2 (RDES2)

| Bit  | Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–0 | Buffer 1 Address Pointer | These bits indicate the physical address of Buffer 1. There are no limitations on the buffer address alignment except for the following condition: The DMA uses the configured value for its address generation when the RDES2 value is used to store the start of frame. Note that the DMA performs a write operation with the RDES2[1:0] bits as 0 during the transfer of the start of frame but the frame data is shifted as per the actual Buffer address pointer. The DMA ignores RDES2[1:0] (corresponding to bus width of 32) if the address pointer is to a buffer where the middle or last part of the frame is stored. |

**Table 23-19:** Receive Descriptor Fields 3 (RDES3)

| Bit  | Name                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–0 | Buffer 2 Address Pointer (Next Descriptor Address) | These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. If RDES1[24] is set, the buffer (Next Descriptor) address pointer must be bus width-aligned (RDES3[1:0] = 0, corresponding to a bus width of 32. LSBs are ignored internally.) However, when RDES1[24] is reset, there are no limitations on the RDES3 value, except for the following condition: The DMA uses the configured value for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3[1:0] (corresponding to a bus width of 32) if the address pointer is to a buffer where the middle or last part of the frame is stored. |

**Table 23-20:** Receive Descriptor Fields 4 (RDES4)

| Bit   | Name           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31–14 | Reserved       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 13    | PTP Version    | When set, indicates that the received PTP message is having the IEEE 1588 version 2 format. When reset, it has the version 1 format. This is valid only if the message type is non-zero.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 12    | PTP Frame Type | When set, this bit indicates that the PTP message is sent directly over Ethernet. When this bit is not set and the message type is non-zero, it indicates that the PTP message is sent over UDP-IPv4 or UDP-IPv6. The information on IPv4 or IPv6 can be obtained from bits 6 and 7.                                                                                                                                                                                                                                                                                                                     |
| 11–8  | Message Type   | These bits are encoded to give the type of the message received.<br>0000 = No PTP message received<br>0001 = SYNC (all clock types)<br>0010 = Follow_Up (all clock types)<br>0011 = Delay_Req (all clock types)<br>0100 = Delay_Resp (all clock types)<br>0101 = Pdelay_Req (in peer-to-peer transparent clock) or Announce (in ordinary or boundary clock)<br>0110 = Pdelay_Resp (in peer-to-peer transparent clock) or Management (in ordinary or boundary clock)<br>0111 = Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) or Signaling (for ordinary or boundary clock)<br>1xxx - Reserved |

**Table 23-20:** Receive Descriptor Fields 4 (RDES4) (Continued)

| Bit | Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                 |
|-----|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | IPv6 Packet Received | When set, this bit indicates that the received packet is an IPv6 packet.                                                                                                                                                                                                                                                                                                                    |
| 6   | IPv4 Packet Received | When set, this bit indicates that the received packet is an IPv4 packet.                                                                                                                                                                                                                                                                                                                    |
| 5   | IP Checksum Bypassed | When set, this bit indicates that the checksum off-load engine is bypassed.                                                                                                                                                                                                                                                                                                                 |
| 4   | IP Payload Error     | When set, this bit indicates that the 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) that the core calculated does not match the corresponding checksum field in the received segment. It is also set when the TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field.                                                       |
| 3   | IP Header Error      | When set, this bit indicates either that the 16-bit IPv4 header checksum calculated by the core does not match the received checksum bytes, or that the IP datagram version is not consistent with the Ethernet Type value.                                                                                                                                                                 |
| 2–0 | IP Payload Type      | These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Off-load Engine (COE). The COE also sets these bits to 2'b00 if it does not process the IP datagram's payload due to an IP header error or fragmented IP.<br>3'b000 = Unknown or did not process IP payload<br>3'b001 = UDP<br>3'b010 = TCP<br>3'b011 = ICMP<br>3'b1xx = Reserved |

**Table 23-21:** Receive Descriptor Fields 6 (RDES6)

## EMAC DMA Transmit Process

The following sections describe how the direct memory access transmit process works on the EMAC controller.

- [Default \(Non-OSF\) Mode](#)
- [OSF Mode Enabled](#)
- [Transmit Frame Processing](#)
- [Transmit Polling Suspended](#)

## Default (Non-OSF) Mode

The transmit DMA engine in default mode proceeds as follows:

1. The application sets up the transmit descriptor (using TDES0- TDES3) and sets the OWN bit (TDES0) after setting up the corresponding data buffer(s) with Ethernet frame data.
2. Once the ST bit (operation mode register [13]) is set, the DMA enters the Run state.
3. While in the Run state, the DMA polls the transmit descriptor list for frames requiring transmission. After polling starts, it continues in either sequential descriptor ring order or chained order. If the DMA detects a descriptor flagged as owned by the application, or if an error condition occurs, transmission is suspended and both the transmit buffer unavailable (DMA\_STAT [2]) and normal interrupt summary (DMA\_STAT [16]) bits are set. The transmit engine proceeds to Step 9.
4. If the acquired descriptor is flagged as owned by DMA (TDES0 [31] = 1#b1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor.
5. The DMA fetches the transmit data from the application memory and transfers the data to the MFL for transmission.
6. If an Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps 3, 4, and 5 are repeated until the end-of-Ethernet-frame data is transferred to the MFL.
7. When frame transmission is complete, if IEEE 1588 time stamping was enabled for the frame (as indicated in the transmit status) the time-stamp value obtained from MFL is written to the transmit

descriptor (TDES2 and TDES3) that contains the end-of-frame buffer. The status information is then written to this transmit descriptor (TDES0). Because the Own bit is cleared during this step, the application now owns this descriptor. If time stamping was not enabled for this frame, the DMA does not alter the contents of TDES2 and TDES3.

8. Transmit Interrupt (DMA\_STAT [0]) is set after completing transmission of a frame that has Interrupt on Completion (TDES1 [31]) set in its Last Descriptor. The DMA engine then returns to Step 3.
9. In the Suspend state, the DMA tries to re-acquire the descriptor (and thereby return to Step 3) when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared.

**NOTE:** If the OSF bit is not set, the actual Inter Frame Gap (IFG) may be seen as more than as programmed in the MAC configuration register.

## OSF Mode Enabled

While in the Run state, the transmit process can simultaneously acquire two frames without closing the Status descriptor of the first (if the OSF bit is set in the DMA\_OPMODE [2]). As the transmit process finishes transferring the first frame, it immediately polls the Transmit Descriptor list for the second frame. If the second frame is valid, the transmit process transfers this frame before writing the first frame status information.

In OSF mode, the run state transmit DMA operates in the following sequence:

1. The DMA operates as described in steps 1-6 of the TxDMA (default mode).
2. Without closing the previous frame's last descriptor, the DMA fetches the next descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into suspend mode and skips to Step 7.
4. The DMA fetches the transmit frame from the application memory and transfers the frame to the MFL until the End-of-Frame data is transferred, closing the intermediate descriptors if this frame is split across multiple descriptors.
5. The DMA waits for the previous frame's frame transmission status and time stamp. Once the status is available, the DMA writes the time stamp to TDES2 and TDES3, if such time stamp was captured (as indicated by a status bit). The DMA then writes the status, with a cleared OWN bit, to the corresponding TDES0, thus closing the descriptor. If time stamping was not enabled for the previous frame, the DMA does not alter the contents of TDES2 and TDES3.
6. If enabled, the transmit interrupt is set; the DMA fetches the next descriptor, and then proceeds to Step 3 (when status is normal). If the previous transmission status shows an underflow error, the DMA goes into suspend mode (Step 7).
7. In suspend mode, if a pending status and time stamp are received from the MFL, the DMA writes the time stamp (if enabled for the current frame) to TDES2 and TDES3, then writes the status to the corresponding TDES0. It then sets relevant interrupts and returns to suspend mode.

8. The DMA can exit suspend mode and enter the run state (go to Step 1 or Step 2 depending on pending status) only after receiving a transmit poll demand (DMA\_TXPOLL).

**NOTE:** If OSF bit is set, the DMA fetches the next descriptor in advance before closing the current descriptor. Therefore the descriptor chain should have more than two different descriptors for proper operation.

**NOTE:** If the OSF bit is set, the DMA starts fetching the second frame immediately after completing the transfer of the first frame to the FIFO. It does not wait for the status to be updated. In the meantime the MFL receives the second frame into the FIFO while transmitting the first frame. The difference in cycles will not be seen for the first descriptor, because the time taken for the complete descriptor processing remains the same whether OSF is set or not. The difference is seen only for the following descriptor as the processing of that descriptor is started earlier.

## Transmit Frame Processing

The Transmit DMA Engine expects that the data buffers contain complete Ethernet frames, excluding preamble, pad bytes, and FCS fields. The destination address, source address, and type/length fields contain valid data. If the transmit descriptor indicates that the EMAC CORE must disable CRC or PAD insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes.

Frames can be data-chained and can span several buffers. Frames must be delimited by the first descriptor (TDES1 [29]) and the last descriptor (TDES1 [30]), respectively.

As transmission starts, the first descriptor must have (TDES1 [29]) set. When this occurs, frame data transfers from the application buffer to the transmit FIFO. Concurrently, if the current frame has the Last Descriptor (TDES1 [30]) cleared, the transmit process attempts to acquire the next descriptor. The transmit process expects this descriptor to have TDES1 [29] clear. If TDES1 [30] is clear, it indicates an intermediary buffer. If TDES1 [30] is set, it indicates the last buffer of the frame.

After the last buffer of the frame has been transmitted, the DMA writes back the final status information to the transmit descriptor 0 (TDES0) word of the descriptor that has the last segment set in transmit descriptor 1 (TDES1 [30]). At this time, if interrupt on completion (TDES1 [31]) was set, transmit interrupt (DMA\_STAT [0]) is set, the next descriptor is fetched, and the process repeats.

Actual frame transmission begins after the MFL transmit FIFO has reached either a programmable transmit threshold (DMA\_OPMODE [16:14]), or a full frame is contained in the FIFO. There is also an option for store and forward mode (DMA\_OPMODE [21]). Descriptors are released (OWN bit TDES0 [31] clears) when the DMA finishes transferring the frame.

## Transmit Polling Suspended

Transmit polling may be suspended by either of the following conditions:

1. The DMA detects a descriptor owned by the application (TDES0 [31] =0).
2. A frame transmission is aborted when a transmit error due to underflow is detected. The appropriate transmit descriptor 0 (TDES0) bit is set.

If the second condition occurs, both abnormal interrupt summary ([15]) and transmit underflow bits ([5]) are set and the information is written to transmit descriptor 0, causing the suspension. If the DMA goes into SUSPEND state due to the first condition then both Normal Interrupt Summary ([16]) and Transmit Buffer Unavailable ([2]) are set.

In both cases, the position in the transmit list is retained. The retained position is that of the descriptor following the last descriptor closed by the DMA.

The driver must explicitly issue a transmit poll demand command after rectifying the suspension cause. If the first condition occurs, the driver must give descriptor ownership to the DMA and then issue a poll demand command, in order to resume the transfer.

## EMAC DMA Receive Process

The following sections describe how the direct memory access receive process works on the EMAC controller.

- [Receive Frame Processing](#)
- [Receive Descriptor Acquisition](#)
- [Receive Process Suspended](#)

The Receive DMA engine's reception proceeds as follows:

1. The application sets up Receive descriptors (RDES0-RDES3) and sets the OWN bit (RDES0 [31]).
2. Once the SR (DMA\_OPMODE [1]) bit is set, the DMA enters the Run state. While in the Run state, the DMA polls the Receive Descriptor list, attempting to acquire free descriptors. If the fetched descriptor is not free (is owned by the application), the DMA enters the Suspend state and jumps to Step 9.
3. The DMA decodes the receive data buffer address from the acquired descriptors.
4. Incoming frames are processed and placed in the acquired descriptor's data buffers.
5. When the buffer is full or the frame transfer is complete, the Receive engine fetches the next descriptor.
6. If the current frame transfer is complete, the DMA proceeds to Step 7. If IEEE 1588 time stamping is enabled, the DMA writes the time stamp (if available) to the current de. If the DMA does not own the next fetched descriptor and the frame transfer is not complete, the DMA sets the Descriptor Error bit in the RDES0 (unless flushing is disabled). The DMA closes the current descriptor (clears the OWN bit) and marks it as intermediate by clearing the Last Segment (LS) bit in the RDES0 value (marks it as Last Descriptor if flushing is not disabled), then proceeds to Step 8. If the DMA does own the next descriptor but the current frame transfer is not complete, the DMA closes the current descriptor as intermediate and reverts to Step 4.
7. If IEEE 1588 time stamping is enabled, the DMA writes the time stamp (if available) to the current descriptor's RDES2 and RDES3. It then takes the receive frame's status from the MFL and writes the status word to the current descriptor's RDES0, with the Own bit cleared and the last segment bit set.

8. The receive engine checks the latest descriptor's OWN bit. If the host owns the descriptor (OWN bit is 0) the receive buffer unavailable bit (DMA\_STAT [7]) is set and the DMA receive engine enters the Suspended state (Step 9). If the DMA owns the descriptor, the engine returns to Step 4 and awaits the next frame.
9. Before the Receive engine enters the Suspend state, partial frames are flushed from the receive FIFO (you can control flushing using Bit 24 of DMA\_OPMODE).
10. The receive DMA exits the suspend state when a receive poll demand is given or the start of next frame is available from the MFL's Receive FIFO. The engine proceeds to Step 2 and re fetches the next descriptor.

## Receive Frame Processing

The EMAC transfers the received frames to the application memory only when the frame passes the address filter sub-block and frame size is greater than or equal to configurable threshold bytes set for the receive FIFO of MFL, or when the complete frame is written to the FIFO in Store-and-Forward mode.

If the frame fails the address filtering, it is dropped in the EMAC block itself (unless receive all EMAC MACCFG[31] bit is set). Frames that are shorter than 64 bytes, because of collision or premature termination, can be purged from the Receive FIFO.

After 64 bytes (configurable threshold) have been received, the MFL block requests the DMA block to begin transferring the frame data to the Receive Buffer pointed to by the current descriptor. The DMA sets First Descriptor (RDES0 [9]) after the SCB becomes ready to receive the data (if DMA is not fetching transmit data from the application). The descriptors are released when the Own (RDES [31]) bit is reset to 0, either as the data buffer fills up or as the last segment of the frame is transferred to the receive buffer. If the frame is contained in a single descriptor, both last descriptor (RDES [8]) and first descriptor (RDES [9]) are set.

The DMA fetches the next descriptor, sets the last descriptor (RDES [8]) bit, and releases the RDES0 status bits in the previous frame descriptor. Then the DMA sets Receive Interrupt (DMA\_STAT [6]). The same process repeats unless the DMA encounters a descriptor flagged as being owned by the application. If this occurs, the receive process sets receive buffer unavailable (DMA\_STAT [7]) and then enters the suspend state. The position in the receive list is retained.

## Receive Descriptor Acquisition

The Receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted if any of the following conditions is satisfied:

- The receive Start/Stop bit (DMA\_OPMODE [1]) has been set immediately after being placed in the Run state.
- The data buffer of current descriptor is full before the frame ends for the current transfer.
- The controller has completed frame reception, but the current receive descriptor is not yet closed.

- The receive process has been suspended because of an application-owned buffer (RDES0 [31] = 0) and a new frame is received.
- A receive poll demand has been issued.

## Receive Process Suspended

If a new receive frame arrives while the receive process is in suspend state, the DMA re-fetches the current descriptor in the application memory. If the descriptor is now owned by the DMA, the receive process re-enters the Run state and starts frame reception. If the descriptor is still owned by the application, by default, the DMA discards the current frame at the top of the receive FIFO and increments the missed frame counter. If more than one frame is stored in the receive FIFO, the process repeats.

The discarding or flushing of the frame at the top of the receive FIFO can be avoided by setting operation mode register bit 24 (DFF). In such conditions, the receive process sets the receive buffer unavailable status and returns to the Suspend state.

## OWN Bit (Ownership) Semaphore

Usage or ownership of the transmit/receive descriptor between application and EMAC is mutually exclusive. While the EMAC is accessing the descriptor, the application cannot modify it. Conversely, while the host is updating the descriptor, the EMAC cannot use the descriptor's contents. This functionality is implemented through the OWN bit in the transmit/receive descriptor, acting as a semaphore to prevent multiple, simultaneous access to the descriptors.

Following example is based on a use case of 4 WORDs enabled for descriptors (which means the ATDS bit in DMA\_BUSMODE register is not set) and Chain Structure configuration is assumed. However, the explanation of OWN bit semaphore remains consistent irrespective of any particular mode of operation.

### 1. Transmit Own Bit:

- TDES0-TDES3 words implement the transmit descriptors. TDES0 [31] is defined as the OWN bit. When TDES0 [31] is set to 0, this bit indicates that the descriptor is available for the application to update. The application sets up the descriptors, including the buffer addresses, by updating TDES0 through TDES3.
- To release ownership of the descriptor to the EMAC, the application sets the transmit Own bit, TDES0 [31], to 1. TDES0 [31] = 1 indicates that the descriptor is ready for use by the EMAC. The DMA reads the descriptors, then fetches the data to be transmitted from the buffer locations pointed to by the transmit descriptors (TDES2 and TDES3). When either the last data buffer is empty or the end-of-frame is reached, DMA clears the TDES0 [31] bit to 0. Now the transmit descriptor is released to the application for updates.

### 2. Receive Own Bit:

- RDES0-RDES3 words implement the receive descriptors. RDES0 [31] is defined as the Own bit. When RDES0 [31] is set to 0, this bit indicates that the descriptor is available for the application to update. The application sets up the descriptors, including the buffer locations for writing the

received data, by updating RDES0 through RDES3. To give ownership of the descriptor to the EMAC, the host sets the receive Own bit, RDES0 [31], to 1.

- RDES0 [31] = 1 indicates that the descriptor is ready for use by the EMAC. The EMAC's DMA reads the descriptors, then writes the received data to the buffers with locations pointed to by the receive descriptors (RDES2 and RDES3). When either the last data buffer is full or the end-of-frame is reached, DMA clears the RDES0 [31] bit to 0. Now the receive descriptor is released to the application for updates

## Application Data Buffer Alignment

The transmit and receive data buffers do not have any restrictions on start address alignment; the start address for the buffers can be aligned to any of the four bytes. However, the DMA always initiates transfers with address aligned to the bus width with dummy data for the byte lanes not required. This typically happens during the transfer of the beginning or end of an Ethernet frame.

Example for Buffer Read—If the transmit buffer address is 0xFF800002 and 15 bytes need to be transferred, then the DMA reads 5 full words (5 x 32-bit data) from address 0xFF800000. However, when transferring data to the EMAC transmit FIFO, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures it transfers a full 32-bit data to the transmit FIFO, unless it is the end-of-frame.

Example for Buffer Write—If the receive buffer address is 0xFF800002 and 15 bytes of a received frame need to be transferred, then the DMA writes 5 full words (5 x 32-bit data) to address 0xFF800000. However, the first 2 bytes of first transfer and the last 3 bytes of the third transfer have dummy data.

## Buffer Size Calculations

The DMA Engines do not update the size fields in the Transmit and Receive descriptors by itself. The DMA updates only the status fields (RDES0 and TDES0) of the descriptors. The driver has to perform the size calculations. The transmit DMA transfers the exact number of bytes (indicated by buffer size field of TDES1) towards the EMAC CORE. If a descriptor is marked as first (FS bit of TDES1 is set), then the DMA marks the first transfer from the buffer as the start of frame. If a descriptor is marked as last (LS bit of TDES1), then the DMA marks the last transfer from that data buffer as the end-of frame to the EMAC.

The receive DMA transfers data to a buffer until the buffer is full or the end-of frame is received from the MFL. If a descriptor is not marked as last (LS bit of RDES0), then the descriptor's corresponding buffer(s) are full and the amount of valid data in a buffer is accurately indicated by its buffer size field minus the data buffer pointer offset when the FS bit of that descriptor is set. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, then the buffer may not be full (as indicated by the buffer size in RDES1). To compute the amount of valid data in this final buffer, the driver must read the frame length (FL bits of RDES0[29:16]) and subtract the sum of the buffer sizes of the preceding buffers in this frame. The Receive DMA always transfers the start of next frame with a new descriptor.

## EMAC FIFO Layer (EMAC MFL)

The MAC FIFO Layer provides FIFO memory to buffer and regulate the frames between the application system memory and the EMAC CORE. It also enables the data to be transferred between the application clock domain and the EMAC clock domains. The MFL layer has transfer controllers for each direction, namely the Transmit Controller (TxFIFO) and the Receive Controller (RxFIFO). The data path for both directions is 32-bit wide and each controller has a dedicated FIFO.

### FIFO Size

- The transmit FIFO size is fixed and is 256 bytes.
- The receive FIFO sized is fixed and is 128 bytes.

### FIFO Layer Transmit Path

The DMA Engine controls all transactions for the transmit path with the application. Ethernet frames read from the system memory are pushed into the FIFO by the DMA. The frame is then popped out and transferred to the EMAC CORE when triggered. When the end-of-frame is transferred, the status of the transmission is taken from the EMAC CORE and transferred back to the DMA. FIFO-fill level is indicated to the DMA so that it can initiate a data fetch in required bursts from the system memory, through the SCB interface.

When Operate on Second Frame (OSF) is enabled, the MFL receives the second frame into the FIFO while transmitting the first frame. As soon as the first frame has been transferred and the status is sent to DMA. If the DMA has already completed sending the second packet to the MFL, it must wait for the status of the first packet before proceeding to the next frame.

Modes of operation for FIFO transactions:

1. Threshold mode: In this mode as soon as the number of bytes in the FIFO crosses the configured threshold level (or when the end-of-frame is written before the threshold is crossed), the data is ready to be popped out and forwarded to the EMAC core. The threshold level is configured using the TTC bits of the DMA bus mode register.
2. Store-and-Forward mode: In this mode, the MFL pops the frame towards the EMAC core only after a complete frame is stored in the FIFO. If the Tx FIFO size is smaller than the Ethernet frame to be transmitted (such as a Jumbo frame), then the frame is forwarded when the Tx FIFO becomes almost full or when the requested FIFO does not have space to accommodate the requested burst-length. Therefore, the FIFO read controller never stalls in Store and Forward mode even if the Ethernet frame length is bigger than the Tx FIFO depth.

### Transmit FIFO and Half-Duplex Retransmissions

While a frame is being transferred from the FIFO a collision event can occur on the EMAC line interface in Half-Duplex mode. The EMAC then indicates a retry attempt to the MFL by giving the status even before the end-of-frame is transferred from MFL. Then the MFL will enable the retransmission by popping out the frame again from the FIFO.

After more than 96 bytes are popped out of FIFO, the FIFO controller frees up that space and makes it available to the DMA to push in more data. This means that the retransmission is not possible after this threshold is crossed or when the EMAC CORE indicates a late-collision event.

### Transmit FIFO Flush Operation

The EMAC provides a control to the software to flush the Transmit FIFO in the MFL layer through the use of Bit 20 of the Operation Mode register. The Flush operation is immediate and the MFL clears the Transmit FIFO and the corresponding pointers to the initial state even if it is in the middle of transferring a frame to the EMAC CORE. The data which is already accepted by the MAC transmitter will not be flushed. It will be scheduled for transmission and will result in underflow as Transmit FIFO does not complete the transfer of rest of the frame. As in all underflow conditions, a runt frame will be transmitted and observed on the line. The status of such a frame will be marked with both Underflow and Frame Flush events (TDES0 bits 13 and 1).

The MFL layer also stops accepting any data from the application (DMA) during the flush operation. It generates and transfers transmit status words to the application for the number of frames that is flushed inside the MFL (including partial frames). Frames that are completely flushed in the MFL have the Frame Flush Status bit (TDES0 bit 13) set. The MFL completes the flush operation when the application (DMA) accepts all of the status words for the frames that were flushed, and then clears the Transmit FIFO Flush control register bit. At this point, the MFL starts accepting new frames from the application (DMA).

### FIFO Layer Receive Path

The receive controller operates in below sequence:

1. When the EMAC core receives a frame, it pushes in data with the frame start and end indicators. The MFL accepts the data and pushes it into the FIFO.
2. The receive controller takes the data out of the FIFO and sends it to the DMA.
  - In the default Threshold mode, when 64 bytes (configured with `RTC` bits of DMA Operation Mode register) or a full packet of data are received into the FIFO, the receive controller pops out the data and indicates its availability to the DMA. Some error frames may not be dropped, because the error status is received at the end-of-frame, by which time the start of that frame has already been read out of the FIFO.
  - In Rx FIFO Store-and-Forward mode (configured by the `RSF` bit of DMA Operation Mode register), a frame is read out only after being written completely into the Receive FIFO. In this mode, all error frames are dropped (if the EMAC core is configured to do so) such that only valid frames are read out and forwarded to the application.
3. After the end-of-frame is transferred, the status word from EMAC core is also the pushed FIFO. When the status of a partial frame due to overflow is given out, the Frame Length field in the status word is not valid.

## Receive FIFO Multi-Frame Handling

Since the status is available immediately following the data, the MFL is capable of storing any number of frames into the FIFO, as long as it is not full.

## Receive FIFO Error Handling

If the MFL Rx FIFO is full before it receives the end-of-frame data from the EMAC, an overflow is declared, the whole frame (including the status word) is dropped, and the overflow counter in the DMA (Over Flow Counter register) is incremented. This is true even if the Forward Error Frame (FEF bit of DMA Operation Mode register) is set. If the start address of such a frame has already been transferred, the rest of the frame is dropped and a dummy end-of-frame is written to the FIFO along with the status word. The status will indicate a partial frame due to overflow. In such frames, the Frame Length field is invalid.

The MFL Rx control logic can filter error and undersized frames, if enabled (using the DMA Operation Mode register FEF and FUF bits). If the start address of such a frame has already been transferred to the Rx FIFO read controller, that frame is not filtered. The start address of the frame is transferred to the Read Controller after the frame crosses the receive threshold (set by the DMA Operation Mode register RTC bits).

If the MFL Receive FIFO is configured to operate in Store-and-Forward mode, all error frames can be filtered and dropped.

## EMAC CORE

EMAC CORE is the lowest block in the EMAC peripheral and it performs all operations with the external world (PHY chip). It has independent transmit and receive modules that interact with the EMAC FIFO Layer at one end and the PHY chip via RMII interface at the other end. Both the modules have several sub blocks, and are explained in further sections.

Transmission is initiated when the MFL (FIFO Layer) pushes in data with start-of-frame and the CORE subsequently transmitting to the RMII. After the end-of-frame is transferred out, it gives out the status of transmission back to the MFL to be forwarded to application via DMA. A receive operation is initiated when the EMAC detects an SFD on the RMII. The CORE strips the preamble and SFD before proceeding to process the frame. The header fields are checked for the filtering and the FCS field used to verify the CRC for the frame. The frame is dropped in the core if it fails the address filter.

**NOTE:** The “CORE” terminology (written in capitals) is used refer to the internal block of Ethernet peripheral, and should not be confused as “processor core”.

**Table 23-23:** EMAC CORE Related Registers

| Register name                | Related Functionality                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAC Configuration Register   | Establishes receive and transmit operating modes. Important configurations include: <ul style="list-style-type: none"> <li>• Watchdog/Jabber/Jumbo frame sizes.</li> <li>• Inter Frame Gap.</li> <li>• Speed Control – 10/100 Mbps.</li> <li>• Full/Half Duplex.</li> <li>• Loopback Mode.</li> <li>• Checksum Offload.</li> <li>• Enabling TX/RX Engines.</li> </ul>                            |
| MAC Frame Filter Register    | Contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.                                                             |
| Hash Table High/Low Register | A 64-bit Hash table is used for group address filtering. For hash filtering, the contents of the destination address in the incoming frame is passed through the CRC logic, and the upper 6 bits of the CRC register are used to index the contents of the Hash table.                                                                                                                           |
| SMI Address Register         | Controls the management cycles to the external PHY through the Station Management interface. The register also includes field to program the frequency of MDC.                                                                                                                                                                                                                                   |
| SMI Data Register            | Stores write data to be written to the PHY register located at the address specified in SMI Address register. This register also stores read data from the PHY register located at the address specified by SMI Address Register.                                                                                                                                                                |
| Flow Control Register        | Controls the generation and reception of the control (pause command) frames by the EMAC's flow control module. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The Host must make sure that the Activate bit is cleared before writing to the register. |

**Table 23-23:** EMAC CORE Related Registers (Continued)

| Register name                  | Related Functionality                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VLAN Tag Register              | Contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 16.h8100, and the following 2 bytes are compared with the VLAN tag; if a match occurs, it sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1518 bytes to 1522 bytes.                  |
| Debug Register                 | Provides the status of all main modules of the transmit and receive data-paths and the FIFOs. An all-zero status indicates that the MAC core is in idle state (and FIFOs are empty) and no activity is going on in the data-paths.                                                                                                                                                             |
| Interrupt Status Register      | The contents of this register identify the events in the EMAC-CORE that can generate interrupts – MMC and PTP related.                                                                                                                                                                                                                                                                         |
| Interrupt Mask Register        | Enables the program to mask the interrupt signal because of the corresponding PTP event in the Interrupt Status register.                                                                                                                                                                                                                                                                      |
| MAC Address0 High/Low Register | Holds the upper/lower 16 bits of the MAC address of the station. Note that the first DA byte that is received on the RMII interface corresponds to the LS Byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 is the first byte) on the RMII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211. |

**NOTE:** Please refer to the Register Description for the detailed bit-level explanation of the Registers.

**NOTE:** There should not be any further writes to the below registers until the first write is updated. Otherwise, the second write operation will not get updated properly. For correct operation, the delay between two writes to the same register location should be at least 8 cycles of 50MHz RMII REFCLK.

**Table 23-24:** MAC Registers with Consecutive Write Implications

| Registers with Implications for Consecutive Writes |
|----------------------------------------------------|
| Operation Mode Register                            |
| MAC Configuration register                         |
| Hash Table High Register                           |
| Hash Table Low Register                            |

**Table 23-24:** MAC Registers with Consecutive Write Implications (Continued)

| Registers with Implications for Consecutive Writes |
|----------------------------------------------------|
| SMI Address Register                               |
| SMI Data Register                                  |
| Flow Control Register                              |
| VLAN Tag Register                                  |
| MAC Address High Register                          |
| MAC Address Low Register                           |

## EMAC CORE Transmission Engine

The following modules constitute the transmission function (transmission engine components) of the EMAC:

- [Transmit Bus Interface Module \(TBU\)](#)
- [Transmit Frame Controller Module \(TFC\)](#)
- [Transmit Checksum Offload Engine \(TCOE\)](#)
- [Transmit Protocol Engine Module \(TPE\)](#)
- [Transmit Scheduler Module \(STX\)](#)
- [Transmit CRC Generator Module \(CTX\)](#)
- [Transmit Flow Control Module \(FTX\)](#)

### Transmit Bus Interface Module (TBU)

This module interfaces the transmit path of the EMAC CORE with the MAC Layer FIFO interface. This module outputs the Transmit Status to the application at the end of normal transmission or collision.

### Transmit Frame Controller Module (TFC)

The Transmit Frame Controller regulates frames as well as converts the 32-bit input data into an 8-bit stream.

When the number of bytes received from the application falls below 60 (DA+SA+LT+DATA), the state machine automatically appends zeros to the transmitting frame to make the data length exactly 46 bytes to meet the minimum data field requirement of IEEE 802.3. The EMAC can also be programmed not to append any padding.

The Frame Controller receives the computed CRC and appends it as the FCS field to the data being transmitted out. When the EMAC is programmed to not append the CRC value to the end of Ethernet frames, the TFC module ignores the computed CRC. An exception to this rule is that when the EMAC is programmed to append pads for frames (DA+SA+LT+DATA) less than 60 bytes, then the CRC is always appended at the end of padded frame.

### Transmit Checksum Offload Engine (TCOE)

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. Because the most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams, the EMAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the transmit path, and error detection in the receive path.

*The checksum for TCP, UDP, or ICMP is calculated over a complete frame, and then inserted into its corresponding header field. Because of this requirement, this function is enabled only when the Transmit FIFO is configured for Store-and-Forward mode (that is, when the TSF bit is set in DMA Opmode Register. If the MAC is configured for Threshold (cut-through) mode, the Transmit COE is bypassed.*

*You must make sure that the Transmit FIFO is deep enough to store a complete frame before that frame is transferred to the EMAC CORE transmitter. User must enable the checksum insertion only in the frames that are less than the following number of bytes in size (even in the store-and-forward mode): FIFO Depth (256 bytes) – PBL – 3 FIFO Locations, where PBL is the programmed burst-length in DMA Bus mode register.*

### IP Header Checksum

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Ethernet frame's Type field has the value 0x0800 and the IP datagram's Version field has the value 0x4. The input frame's checksum field is ignored during calculation and replaced with the calculated value.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in transmit descriptor word TDES0. This status bit is set whenever the values of the Ethernet Type field and the IP header's Version field are not consistent, or when the Ethernet frame does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

For IPv4 datagrams:

- The received Ethernet type is 0x0800, but the IP header's Version field is not equal to 0x4.
- The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
- The total frame length is less than the value given in the IPv4 Header Length field.

For IPv6 datagrams:

- The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
- The frame ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.

*IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.*

## TCP/UDP/ICMP Checksum

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP.

*See IETF specifications RFC 791, RFC 793, RFC 768, RFC 792, RFC 2460, and RFC 4443 for IPv4, TCP, UDP, ICMP, IPv6, and ICMPv6 packet header specifications, respectively.*

*For non-TCP/UDP/ICMP/ICMPv6 payloads, this checksum engine is bypassed and nothing further is modified in the frame.*

*For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 0x0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 0x0000, an incorrect checksum may be inserted into the packet.*

*Fragmented IP frames (IPv4 or IPv6), IP frames with security features (such as an encapsulated security payload), and IPv6 frames with routing headers are not processed by this engine. The checksum engine bypasses the checksum insertion for such frames even if the checksum insertion is enabled.*

The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. This engine can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input frame. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Descriptor word TDES0. This engine sets the Payload Checksum Error status bit when it detects that the frame has been forwarded to the MAC Transmitter engine in the Store-and-Forward mode without the end-of-frame (EOF) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

Transmit Checksum offloading is enabled by setting the `CIC` field bits [23:22] of TDES0 word in Transmit descriptor.

## Transmit Protocol Engine Module (TPE)

The Transmit Protocol Engine consists of a state-machine that controls the protocol level operation of Ethernet frame transmission. The module performs the following functions to meet the IEEE 802.3 specifications.

- Generates preamble and SFD.
- Generates jam pattern in Half-Duplex mode.
- Jabber timeout.
- Flow control for Half-Duplex mode (back pressure).
- Generates transmit frame status.

When a new frame transmission is requested, the Protocol Engine sends out the preamble and SFD, followed by the data received. The preamble is defined as 7 bytes of '10101010' pattern and the SFD is defined as 1 byte of '10101011' pattern.

The collision window is defined as 1 slot time (512 bit times for 10/100 Mbps). The jam pattern generation is applicable only to Half-Duplex mode, not to Full-Duplex mode. If a collision occurs any time from the beginning of the frame to the end of the CRC field, the state machine sends a 32-bit jam pattern of 0x55555555 on the RMII to inform all other stations that a collision has occurred. If the collision is seen during the preamble transmission phase, it completes the transmission of preamble and SFD and then sends the jam pattern. If the collision occurs after the collision window and before the end of the FCS field, it sends a 32-bit jam pattern and sets the late collision bit in the transmit frame status.

The module maintains a jabber timer (in 10/100-Mbps) to cut off the transmission of Ethernet frames if the TFC module transfers more than 2,048 (default) bytes. The time-out is changed to 10,240 bytes when the Jumbo frame is enabled.

The Transmit state machine uses the deferral mechanism for the flow control (Back Pressure) in Half-Duplex mode. When the application requests to stop receiving frames, the module sends a JAM pattern of 32 bytes whenever it senses a reception of a frame, provided the transmit flow control is enabled. This will result in a collision and the remote station will back off. The application can request a flow control signal by setting BPA bit of EMAC Flow Control Register. If the application requests a frame to be transmitted, then it will be scheduled and transmitted even when the backpressure is activated. Note that if the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur) then the remote stations will abort their transmissions due to excessive collisions.

## Transmit Scheduler Module (STX)

The Transmit Scheduler is responsible for scheduling the frame transmission on the RMII. The two major functions of this module are:

- Maintain the inter-frame gap between two transmitted frames.
- Follow the Truncated Binary Exponential Back-off algorithm for Half-Duplex mode.

The Scheduler maintains an idle period of the configured inter-frame gap (IFG bits of MAC Config Register) between any two transmitted frames. The Scheduler starts its IFG counter as soon as the carrier signal of the RMII goes inactive. In Half-Duplex mode and when IFG is configured for 96 bit times, the Scheduler follows the rule of deference specified in Section 4.2.3.2.1 of the IEEE 802.3 specification. The module resets its IFG counter if a carrier is detected during the first two-thirds (64-bit times for all IFG values) of the IFG interval. If the carrier is detected during the final one third of the IFG interval, the Scheduler continues the IFG count and enables the transmitter after the IFG interval.

### Transmit CRC Generator Module (CTX)

The Transmit CRC Generator module generates CRC for the FCS field of the Ethernet frame (DA + SA + LT + DATA + PAD).

This module calculates the 32-bit CRC for the FCS field of the Ethernet frame. The encoding is defined by the following polynomial:  $G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$ .

### Transmit Flow Control Module (FTX)

The Transmit Flow Control module generates Pause frames and transmits them to the Frame Controller as necessary, in Full-Duplex mode. The application can request the Flow Control module to send a Pause frame by setting the `FCB` bit in the Flow Control register.

If the application has requested for flow control, the Flow Control module will generate and transmit a single Pause frame. The value of the Pause Time in the generated frame contains the programmed Pause Time value in Flow Control Register. To extend the pause or end the pause prior to the time specified in the previously transmitted Pause frame, the application must request another Pause frame transmission after programming the Pause Time register with appropriate value.

If the flow control signal goes inactive prior to the sampling time, the Flow Control module will transmit a Pause frame with zero Pause Time to indicate to the remote end that the receive buffer is ready to receive new data frames.

### EMAC CORE Reception Engine

The following are the functional blocks (reception engine components) in the Receive path of the EMAC core.

- [Receive Protocol Engine Module \(RPE\)](#)
- [Receive CRC Module \(CRX\)](#)
- [Receive Frame Controller Module \(RFC\)](#)
- [Receive Flow Control Module \(FRX\)](#)
- [Receive Checksum Offload Engine \(RCOE\)](#)
- [Receive Bus Interface Unit Module \(RBU\)](#)

- [Address Filtering Module \(AFM\)](#)

## Receive Protocol Engine Module (RPE)

The Protocol Engine consists of the state-machine which strips the incoming preamble and SFD. Once the RXDV signal of the RMII becomes active, the Protocol Engine begins hunting for the SFD field from the receive modifier logic. Until then, the state machine drops the receiving preambles. Once the SFD is detected, it begins sending the data of the Ethernet frame to the Frame Controller, beginning with the first byte following the SFD (Destination Address).

**NOTE:** According to the IEEE 802.3 Ethernet Specifications, the EMAC receiver need not look or check for the preamble pattern. It has to wait only for the SFD pattern to identify the start of a frame. Hence the EMAC receiver will accept a frame even when no preamble is received before the SFD pattern.

The Protocol Engine also decodes the Length/Type field of the receiving Ethernet frame. If the Length/Type field is less than 0x600 and if the MAC is programmed for the auto CRC/PAD stripping option, the state machine sends the data of the frame up to the count specified in the Length/Type field, then starts dropping bytes (including the FCS field).

If the Length/Type field is greater than or equal to 0x600, the Protocol Engine will send all received Ethernet frame data to the Frame Controller, irrespective of the value on the programmed auto-CRC strip option.

As a default, the EMAC is programmed for watchdog timer to be enabled, that is, frames above 2,048 (10,240 if Jumbo Frame is enabled) bytes (DA + SA + LT + DATA + PAD + FCS) are cut off at the Protocol Engine. This feature can be disabled by programming the Watchdog Disable in EMAC Configuration register. However even if the watchdog timer is disabled, frames greater than 16 KB in size are cut off and a watchdog time-out status is given.

The EMAC supports loopback of transmitted frames onto its receiver. As a default, the EMAC loopback function is disabled, but this feature can be enabled by programming the EMAC Configuration register, Loopback bit.

At the end of every received frame, the Protocol Engine generates received frame status and sends it to the Frame Controller. Control, missed frame, and filter fail status are added to the receive status in the Frame Controller.

## Receive CRC Module (CRX)

The Receive CRC Module checks for any CRC error in the receiving frame.

This module calculates the 32-bit CRC for the received frame that includes the Destination address field through the FCS field (DA+SA+LT+DATA+PAD+FCS). The encoding is defined by the following generating polynomial.

- $G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$

Irrespective of the auto pad/CRC strip, the CRC module receives the entire frame to compute the CRC check for received frame.

### Receive Frame Controller Module (RFC)

The main functions of the Frame Controller are:

- Converting the 8-bit stream data to 32-bit data.
- Frame filtering.
- Attaching the calculated IP Checksum.
- Update the Receive Status.

If the RA bit of the EMAC Frame Filter register is set, the RFC module initiates the data transfer as soon as possible. At the end of the data transfer, the Frame Controller sends out the received frame status that includes the Address Filtering Pass / Fail status.

If the RA bit is reset, the Frame Controller performs frame filtering based on the destination/source address (the application still needs to perform another level of filtering if it decides not to receive any bad frames like runt, CRC error frames, etc. After receiving the destination/source address bytes, the Frame Controller checks the filter-fail signal from the AFM module for an address match. On detecting a filter-fail from AFB, the frame is dropped and not transferred to the application.

### Receive Flow Control Module (FRX)

The Receive Flow Controller detects the receiving Pause frame and pauses the frame transmission for the delay specified within the received Pause frame. The Flow Controller is enabled only in Full-Duplex mode. The Pause frame detection function can be enabled or disabled with the RFE bit of EMAC Flow Control Register.

Once the receive flow control is enabled, the Flow Controller begins monitoring the received frame destination address for any match with the multicast address of the control frame (0x0180C2000001). If a match is detected, it indicates to the Frame Controller, that the destination address of the received frame matches the reserved control frame destination address. The RFC module then decides whether or not to transfer the received control frame to the application, based on the (PCF) bit setting of EMAC Frame Filter register.

The Receive Flow Controller also decodes the Type, Op-code, and Pause Timer field of the receiving control frame. If the byte count of the frame status indicates 64 bytes, and if there is no CRC error, the Flow Controller requests the MAC transmitter to pause the transmission of any data frame for the duration of the decoded Pause Time value, multiplied by the slot time (64 byte times). Meanwhile, if another Pause frame is detected with a zero Pause Time value, the module resets the Pause Time and gives another pause

request to the Transmitter. If the received control frame matches neither the Type field (0x8808), Opcode (0x00001), nor byte length (64 bytes), or if there is a CRC error, the module does not generate a Pause request to Transmitter.

In the case of a pause frame with a multicast destination address, the Frame Controller filters the frame based on the address match from the Flow Controller. For a pause frame with a unicast destination address, the filtering in the FRX module depends on whether the Destination Address matched the contents of the MAC Address Register 0 and the UP Bit of EMAC Flow Control Register is set (detecting a pause frame even with a unicast destination address). The PCF register bits (Bit [7:6] of EMAC Frame Filter Register) controls the filtering for control frames in addition to the Address filter module.

### Receive Checksum Offload Engine (RCOE)

When checksum offloading is enabled, both IPv4 and IPv6 frames in the received Ethernet frames are detected and processed for data integrity. User can enable this module by setting the IPC bit in the EMAC Configuration register. The EMAC receiver identifies IPv4 or IPv6 frames by checking for value 0x0800 or 0x86DD, respectively, in the received Ethernet frames' Type field. This identification applies to VLAN-tagged frames as well. *Extended descriptor mode (8 x32-bit words) must be enabled to get the IPC checksum engine status in RDES4.* Status can be checked by polling the bit 0 of RDES0 word of Receive Descriptor and then if this bit is set, further parsing bits [7:0] of RDES4 word.

The Receive Checksum Offload engine calculates IPv4 header checksums and checks if they match the received IPv4 header checksums. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received frame does not have enough bytes, as indicated by the IPv4 header's Length field (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP/UDP/ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not tally to the expected payload length given in the IP header.

**NOTE:** COE engine bypasses the payload of fragmented IP datagrams, IP datagrams with security features, IPv6 routing headers, and payloads other than TCP, UDP or ICMP. This information (whether the checksum engine is bypassed or not) is given in the receive status.

The right meaning of Checksum related errors can be understood with the below bit combination in receive descriptors (Frame Status with Full Checksum Offload Engine Enabled and Advanced Timestamps not Enabled):

**Table 23-25:** Checksum error status

| IEEE802.3 Frame: bit 5 of RDES0 | Header Checksum Error: bit 3 of RDES4 | Payload Checksum Error: bit 4 of RDES4 | Frame Status                                                                                                   |
|---------------------------------|---------------------------------------|----------------------------------------|----------------------------------------------------------------------------------------------------------------|
| 0                               | 0                                     | 0                                      | The frame is an IEEE 802.3 frame (Length field value is less than 0x0600).                                     |
| 1                               | 0                                     | 0                                      | IPv4/IPv6 Type frame in which no checksum error is detected.                                                   |
| 1                               | 0                                     | 1                                      | IPv4/IPv6 Type frame in which a payload checksum error (as described for PCE) is detected                      |
| 1                               | 1                                     | 0                                      | IPv4/IPv6 Type frame in which IP header checksum error (as described for IPC HCE) is detected.                 |
| 1                               | 1                                     | 1                                      | IPv4/IPv6 Type frame in which both PCE and IPC HCE is detected.                                                |
| 0                               | 0                                     | 1                                      | IPv4/IPv6 Type frame in which there is no IP HCE and the payload check is bypassed due to unsupported payload. |
| 0                               | 1                                     | 1                                      | Type frame which is neither IPv4 or IPv6 (COE bypasses the checksum check completely)                          |
| 0                               | 1                                     | 0                                      | Reserved                                                                                                       |

### Receive Bus Interface Unit Module (RBU)

The Receive Bus Interface Unit (RBU) constructs the 32-bit data received from the Frame Controller into a 32-bit FIFO based protocol.

### Address Filtering Module (AFM)

The Address Filtering (AFM) module performs the destination checking function on all received frames and reports the address filtering status to the Frame Controller. The address checking is based on different parameters (Frame Filter register) chosen by the application. These parameters are inputs to the AFM module as control signals, and the AFM module reports the status of the address filtering based on the combination of these inputs. The AFM module also reports whether the receiving frame is a multicast

frame or a broadcast frame, as well as the address filter status. The AFM module uses the station's physical (MAC) address and the Multicast Hash table for address checking.

- Hash or Perfect Address Filter:
  - The Destination Address filter can be configured to pass a frame when its Destination Address matches either the Hash filter or the Perfect filter by setting the HPF bit of the Frame Filter register and setting the corresponding HUC or HMC bits. This configuration applies to both unicast and multicast frames. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to the received frame.
  - *Hash filtering is not perfect filtering because a 48-bit MAC address is reduced to a 6-bit hash value. Consequently, there may be instances where more than one address has the same hash value.*
- Unicast Destination Address Filter:
  - The AFM supports 1 MAC address for unicast perfect filtering. If perfect filtering is selected (HUC bit of Frame Filter register is reset), the AFM compares all 48 bits of the received unicast address with the programmed MAC address for any match.
  - In Hash filtering mode (When HUC bit is set), the AFM performs imperfect filtering for unicast addresses using a 64-bit Hash table. For hash filtering, the AFM uses the upper 6 bits CRC of the received destination address to index the content of the Hash table. A value of '000000' selects Bit 0 of the selected register, and a value of 111111 selects Bit 63 of the Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast frame is said to have passed the Hash filter; otherwise, the frame has failed the Hash filter.
- Multicast Destination Address Filter:
  - The EMAC can be programmed to pass all multicast frames by setting the PM bit in the Frame Filter register. If the PM bit is reset, the AFM performs the filtering for multicast addresses based on the HMC bit of Frame Filter register. In Perfect Filtering mode, the multicast address is compared with the programmed MAC Destination Address register. Group address filtering is also supported.
  - In Hash filtering mode, the AFM performs imperfect filtering using a 64-bit Hash table. For hash filtering, the AFM uses the upper 6 bits CRC of the received multicast address to index the content of the Hash table. A value of '000000' selects Bit 0 of the selected register and a value of '111111' selects Bit 63 of the Hash Table register. If the corresponding bit is set to 1, then the multicast frame is said to have passed the Hash filter; otherwise, the frame has failed the Hash filter.
- Broadcast Address Filter:
  - The AFM doesn't filter any broadcast frames in the default mode. However, if the EMAC is programmed to reject all broadcast frames by setting the DBF bit in the Frame Filter register, the AFM asserts the Filter fail signal, whenever a broadcast frame is received.
- Inverse Filtering Operation:

- There is an option to invert the filter-match result at the final output. This is controlled by the **DAIF** bit of the Frame Filter register. The **DAIF** bit is applicable for both Unicast and Multicast DA frames. The result of the unicast / multicast destination address filter is inverted in this mode.

## Destination Address Filtering

The following table provides possible address filtering scenarios with the EMAC AFM module.

**Table 23-26:** Destination Address Filtering

| Frame Type | PR | HPF | HUC | HMC | DAIF | PM | DB | DA Filter Operation                         |
|------------|----|-----|-----|-----|------|----|----|---------------------------------------------|
| Broadcast  | 1  | X   | X   | X   | X    | X  | X  | Pass                                        |
|            | 0  | X   | X   | X   | X    | X  | 0  | Pass                                        |
|            | 0  | X   | X   | X   | X    | X  | 1  | Fail                                        |
| Unicast    | 1  | X   | X   | X   | X    | X  | X  | Pass all frames.                            |
|            | 0  | X   | 0   | 0   | X    | X  | X  | Pass on Perfect/Group filter match.         |
|            | 0  | X   | 0   | 1   | X    | X  | X  | Fail on Perfect/Group filter match.         |
|            | 0  | 0   | 1   | 0   | X    | X  | X  | Pass on Hash filter match.                  |
|            | 0  | 0   | 1   | 1   | X    | X  | X  | Fail on Hash filter match.                  |
|            | 0  | 1   | 1   | 0   | X    | X  | X  | Pass on Hash or Perfect/Group filter match. |
|            | 0  | 1   | 1   | 1   | X    | X  | X  | Fail on Hash or Perfect/Group filter match. |
| Multicast  | 1  | X   | X   | X   | X    | X  | X  | Pass all frames.                            |
|            | X  | X   | X   | X   | X    | 1  | X  | Pass all frames.                            |

**Table 23-26:** Destination Address Filtering (Continued)

| Frame Type | PR | HPF | HUC | HMC | DAIF | PM | DB | DA Filter Operation                                                                   |
|------------|----|-----|-----|-----|------|----|----|---------------------------------------------------------------------------------------|
|            | 0  | X   | X   | 0   | 0    | 0  | X  | Pass on Perfect/Group filter match and drop PAUSE control frames if PCF = 0x.         |
|            | 0  | 0   | X   | 0   | 1    | 0  | X  | Pass on Hash filter match and drop PAUSE control frames if PCF = 0x.                  |
|            | 0  | 1   | X   | 0   | 1    | 0  | X  | Pass on Hash or Perfect/Group filter match and drop PAUSE control frames if PCF = 0x. |
|            | 0  | X   | X   | 1   | 0    | 0  | X  | Fail on Perfect/Group filter match and drop PAUSE control frames if PCF = 0x.         |
|            | 0  | 0   | X   | 1   | 1    | 0  | X  | Fail on Hash filter match and drop PAUSE control frames if PCF = 0x.                  |
|            | 0  | 1   | X   | 1   | 1    | 0  | X  | Fail on Hash or Perfect/Group filter match and drop PAUSE control frames if PCF = 0x. |

## EMAC Station Management Interface (SMI)

The IEEE 802.3 MII Station Management interface (applicable for RMII as well), also known as MDIO management interface, allows the Blackfin processor to monitor and control one or more external Ethernet physical-layer transceivers (commonly called PHYs). The management interface physically consists of a 2-wire serial connection composed of the MDC (management data clock) output signal and the MDIO (management data input/output) bidirectional data signal.

The application can select one of the 32 PHYs and one of the 32 registers within any PHY and send control data or receive status information. Only one register in one PHY can be addressed at any given time. All the transfers are initiated by the EMAC CORE, and the PHY chip only acts as a slave device.

Standard PHY control and status registers typically provide device capability status bits (for example, auto-negotiation, duplex modes, 10/100 speeds and protocols), device status bits (for example, auto-negotiation complete, link status, remote fault), and device control bits (for example, reset, speed selection, loopback, and auto-negotiation start). The features supported by the PHY may be determined at power-up by an MDIO read access (at default rates) of device capabilities in PHY status registers.

The MII management logical interface specifies:

- A set of 16-bit device control/status registers within PHYs, including both required registers with standardized bit definitions as well as optional vendor-specified registers.
- A 5-bit device addressing scheme which allows the MAC to select one of up to 32 externally-connected PHY devices.
- A 5-bit register addressing scheme for selecting the target register within the addressed device.
- A transfer frame protocol for 16-bit read and write accesses to PHY registers via the MDC and MDIO signals under control of the MAC.

**Table 23-27:** Station Management Interface pins

| Station Management Interface pins | Pin Description                                                                                                |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------|
| MDIO - Management Data IO         | A periodic clock that runs at a maximum period of 400ns. Always Driven by the EMAC to PHY.                     |
| MDC - Management Data Clock       | Data signal driven by EMAC or PHY, depending on write or read access with respect to EMAC; synchronous to MDC. |

## MDC Clock Frequency

The frequency of MDC is determined by the `CSR` field in the `SMI_ADDR` register. The clock range selection determines the frequency of the clock relative to the SCLK frequency. The suggested range of SCLK frequency applicable for each value of `CSR` field is given below. The programmability based on SCLK frequency range ensures that the MDC clock frequency range is within the IEEE specifications of 1.0 MHz - 2.4 MHz. However, EMAC MDC can also support higher frequencies for PHY devices that support the same.

**Table 23-28:** MDC clock frequency selection

| CSR Selection | Programmed SCLK frequency range | Frequency of MDC | Min and Max MDC Freq, as per specifications |
|---------------|---------------------------------|------------------|---------------------------------------------|
| 0000          | 60-100 MHz                      | SCLK/42          | MIN= 1.43MHz and MAX= 2.39 MHz              |
| 0001          | 100-125 MHz                     | SCLK/62          | MIN = 1.61MHz and MAX=2.01MHz               |
| 0010          | 20-35 MHz                       | SCLK/16          | MIN = 1.25MHz and MAX=2.19MHz               |
| 0011          | 35-60 MHz                       | SCLK/26          | MIN = 1.35MHz and MAX=2.31MHz               |

MDIO data transfer parameters are given below. Write and Read sequences provided further are based on these parameters.

**Table 23-29:** MDIO frame parameters

| Parameter | Description                                                                            |
|-----------|----------------------------------------------------------------------------------------|
| IDLE      | The MDIO line is three-state (Noted as ' Z' in sequence); there is no clock on MDC.    |
| PREAMBLE  | 32 continuous bits, each of value 1.                                                   |
| START     | Start-of-frame is 01 .                                                                 |
| OPCODE    | 10 for Read and 01 for Write.                                                          |
| PHY ADDR  | 5-bit address select for one of 32 PHYs (Noted as ' AAAAA' in sequence).               |
| REG ADDR  | Register address in the selected PHY (Noted as ' RRRRR' in sequence).                  |
| TA        | Turnaround is Z0 for Read and 10 for Write (Z = High Impedance).                       |
| DATA      | Any 16-bit value. Driven by MAC or PHY based on direction (Noted as ' DDD . . . DDD'). |

Table 23-30: MDIO Write data sequence

| IDLE | PREAMBLE  | START | OPCODE | PHY ADDR | REG ADDR | TA | DATA          | IDLE |
|------|-----------|-------|--------|----------|----------|----|---------------|------|
| Z    | 111...111 | 01    | 01     | AAAAA    | RRRRR    | 10 | DDD...D<br>DD | Z    |

Table 23-31: MDIO Read data sequence

| IDLE | PREAMBLE  | START | OPCODE | PHY ADDR | REG ADDR | TA | DATA          | IDLE |
|------|-----------|-------|--------|----------|----------|----|---------------|------|
| Z    | 111...111 | 01    | 10     | AAAAA    | RRRRR    | Z0 | DDD...D<br>DD | Z    |

SMI Write Operation

When the user sets the Write and Busy bits in SMI\_ADDR Register, the Station Management Interface initiates a Write operation into the PHY registers with the Management Frame Format (the PHY address, the register address in PHY, and the write data) specified in the IEEE specifications (Section 22.2.4.5 of IEEE Standard). The application should not change the SMI Address register contents or the SMI Data register while the transaction is ongoing. Write operations to the SMI Address register or the SMI Data Register during the transfer period are ignored (while the Busy bit is high), and the transaction is completed without any error. After the Write operation has completed, the SMI indicates the same by resetting the Busy bit. The EMAC drives the MDIO line for the complete duration of the frame.

Figure 23-9: SMI Write operation via MDIO/MDC pins

SMI Read Operation

When the user sets the Busy bit in SMI\_ADDR Register with the SMI Write bit as '0', the Station Management Interface transfers the PHY address and the register address in PHY to the SMI to initiate a Read operation in the PHY registers. The application should not change the SMI Address register contents or the SMI Data register while the transaction is ongoing. Write operations to the SMI Address register or

SMI Data Register during the transfer period are ignored (while Busy bit is high) and the transaction is completed without any error. After the Read operation has completed, the SMI indicates this by resetting the Busy bit and updates the SMI Data register with the data read from the PHY. The EMAC drives the MDIO line for the complete duration of the frame except during the Data fields when the PHY is driving the MDIO line.

**Figure 23-10:** SMI Read operation via MDIO/MDC pins

## EMAC Management Counters (MMC)

The EMAC provides a comprehensive set of 32-bit MAC management counters. These counters are used for gathering statistics on the received and transmitted frames. The MMC sub-block also includes a control register for controlling the behavior of the counters, two 32-bit registers containing interrupts generated (receive and transmit), and two 32-bit registers containing masks for the Interrupt Register (receive and transmit).

The Receive MMC counters are updated for frames that are passed by the Address Filtering sub-block in EMAC CORE. Statistics of frames that are dropped by the AFM module are not updated unless they are runt frames of less than 6 bytes (Destination Address bytes are not received fully). The Module is also capable of gathering statistics on encapsulated IPv4, IPv6, and TCP, UDP, or ICMP payloads in received Ethernet frames.

Please refer to the Register Descriptions for all the statistical counters available in EMAC. The MMC register naming conventions are as follows:

- TX as a prefix or suffix indicates counters associated with transmission.
- RX as a prefix or suffix indicates counters associated with reception.
- \_G as a suffix indicates registers that count good frames only.
- \_GB as a suffix indicates registers that count frames regardless of whether they are good or bad.

Transmitted frames are considered “good” if transmitted successfully. In other words, a transmitted frame is good if the frame transmission is not aborted due to any of the following errors:

- Jabber Timeout
- No Carrier/Loss of Carrier

- Late Collision
- Frame Underflow
- Excessive Deferral
- Excessive Collision

Received frames are considered “good” if none of the following errors exists:

- CRC error
- Runt Frame (shorter than 64 bytes)
- Alignment error
- Length error (non-Type frames only)
- Out of Range (non-Type frames only, longer than maximum size)

The maximum frame size depends on the frame type, as follows:

- Untagged frame maxsize = 1518
- VLAN Frame maxsize = 1522
- Jumbo Frame maxsize = 9018
- Jumbo VLAN Frame maxsize = 9022

The Module includes a Control Register for Preset, Freeze and Roll-Over of counters. Additional configuration include `RDRST` bit for enabling an auto-reset feature whenever the Counters are read and `RST` bit for resetting all the counters. Please refer to the Register Descriptions for detailed bit level description of MMC Control Register.

The MMC can also trigger an interrupt, when the corresponding bits are enabled in the Mask Registers of Transmit, Receive and IPC, and when the particular counter reaches half/full. The status is also updated in the corresponding Interrupt register.

### **MMC Receive Interrupt Register**

The MMC Receive Interrupt Register maintains the interrupts that are generated when receive statistic counters reach half their maximum values (0x80000000), and when they cross their maximum values (0xFFFFFFFF). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt Register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits [7:0]) of the respective counter must be read in order to clear the interrupt bit.

### **MMC Transmit Interrupt Register**

The MMC Transmit Interrupt Register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x80000000), and when they cross their maximum values

(0xFFFFFFFF). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt Register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits [7:0]) of the respective counter must be read in order to clear the interrupt bit.

### MMC Receive Checksum Offload Interrupt Register

The MMC Receive Checksum Offload Interrupt Register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x80000000), and when they cross their maximum values (0xFFFFFFFF). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32-bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (bits [7:0]) must be read to clear the interrupt bit.

## EMAC Precision Time Protocol (PTP) Engine

The following sections describe the Precision Time Protocol engine.

### Introduction to IEEE1588 and PTP Engine

Ethernet MAC peripheral includes a PTP Engine to assist applications requiring time synchronization. PTP module is tightly integrated with EMAC CORE, in order to aid hardware time stamping defined as per IEEE1588 2002/2008 standards. Applications can make use of accurate hardware time stamps via TCP/IP stacks (if using Network layer communication) or via Ethernet device drivers (if using MAC layer communication), to exchange time information across devices connected over network.

### Basic Concept of IEEE1588

Many systems require two independent devices to operate in a time synchronized fashion. If each system were to rely solely on its own oscillator, differences between the specific characteristics and operating conditions of the individual oscillators would limit the ability of the clocks to operate synchronously. To serve applications requiring synchronized clocks, a periodic correction mechanism need to be applied.

A simple way to synchronize multiple systems is to choose one system as a Master, who will be having the best clock. Master will broadcast the clock and timing information to other systems (say slaves) and then the slaves will adjust their clock and timing according to that of Master. But, this straight forward method has limitations, such as, Master cannot broadcast the time at infinitesimal intervals, Path delay (propagation delay) exists between Master and a slave, and the delay varies between each slave and Master.

IEEE 1588 (also known as Precision Time Protocol or PTP) standard specifies a protocol used to synchronize time and clock of multiple devices, dispersed but interconnected by any communication, for example, Ethernet (IEEE 802.3). According to the protocol timing messages are exchanged between two devices (both the devices should have same representation of its system time), and then one of the device calculates its drift from other device and corrects its system time. The protocol takes care of path delay between devices and can also help synchronize clocks of multiple devices. Hence all the limitations mentioned above are not seen in this protocol.

IEEE 1588 was published in 2002 where four types of timing messages were defined: Sync, Follow\_Up, Delay\_Req, and Delay\_Resp. Here the protocol synchronizes two or more devices where one is Master and others are slaves. Sync, Follow\_Up, and Delay\_Resp messages are sent from the Master device to Slave device in the system, while Delay\_Req message is sent from a Slave device to Master device. More information on IEEE 1588-2002 is given below.

In 2008 a newer version of IEEE 1588 was introduced which provides further mechanisms to measure the peer-to-peer delay. Three additional timing messages (PdelayReq, PdelayResp, and PdelayRespFollowup) were added to implement peer-to-peer synchronization. More information on IEEE 1588-2008 is given below.

## PTP Engine in EMAC

In IEEE 1588 protocol, for calculation of drift in time between two Ethernet devices, the device should note down its system time whenever a timing message is sent or received. Due to the indeterministic delay of a node's software system, the software is unable to capture an accurate time when the message is sent or received. However, the hardware is capable of monitoring the signal on the communication media and therefore getting accurate message arrival/departure time.

The PTP (Precision Time Protocol) module, closely integrated with the EMAC module provides hardware assistance to implement both the IEEE 1588-2002 and IEEE 1588-2008 standard on Ethernet (IEEE 802.3). It takes one input clock signal as its PTP clock and maintains the timing information (called System Time) at the level of nanoseconds.

PTP module includes hardware for clock and System Time adjustment. The System Time is physically represented by Pulse -Per-Second (PPS) signal. PPS can be programmed to a fixed frequency or provide flexibility to the signal in terms of pulse width, interval, start and stop time of the signal. PTP module can be programmed to trigger an alarm interrupt when System Time reaches specified time.

PTP module can be programmed to detect different types of received frames, capture System Time and timestamp those frames with captured System Time. User can program any frame such that PTP module will capture the System Time when it is transmitted. PTP module can also capture System Time when an event is detected on Auxiliary Snapshot Trigger input pin.

## IEEE 1588-2002 Overview

The IEEE 1588-2002 standard defines a protocol, Precision Time Protocol (PTP) that enables precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The PTP applies to systems communicating by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

The PTP is transported over UDP/IP. The system or network is classified into Master and Slave nodes for distributing the timing/clock information. Figure below shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

**Figure 23-11:** IEEE 1588-2002 PTP Process

As shown in Figure above, the PTP uses the following process:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the master's reference time information. The time at which this message leaves the master's system is  $t_1$ . This time must be captured by the Master, for Ethernet ports, at RMII.
2. The slave receives the Sync message and also captures the exact time,  $t_2$ , using its timing reference.
3. The master sends a Follow\_up message to the slave, which contains  $t_1$  information for later use.
4. The slave sends a Delay\_Req message to the master, noting the exact time,  $t_3$ , at which this frame leaves the RMII.
5. The master receives the message, capturing the exact time,  $t_4$ , at which it enters its system.
6. The master sends the  $t_4$  information to the slave in the Delay\_Resp message.
7. The slave uses the four values of  $t_1$ ,  $t_2$ ,  $t_3$ , and  $t_4$  to synchronize its local timing reference to the master's timing reference.

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at

the RMI. This timing information must be captured and returned to the software for the proper implementation of PTP with high accuracy.

### **IEEE 1588-2008 Advanced Timestamps**

In addition to the basic timestamp features mentioned in IEEE 1588-2002 Timestamps, the EMAC supports the following advanced timestamp features defined in the IEEE 1588-2008 standard.

- Support for the IEEE 1588-2008 (Version 2) timestamp format.
- Provides an option to take snapshot of all frames or only PTP type frames.
- Provides an option to take snapshot of only event messages.
- Provides an option to select the node to be a Master or Slave.
- Identifies the PTP message type, version, and PTP payload in frames sent directly over Ethernet and sends the status.
- Provides an option to run nanoseconds time in digital or binary format.

### **Peer-to-Peer (P2P) PTP Message Support**

The IEEE 1588-2008 version supports Peer-to-Peer PTP (Pdelay) message in addition to SYNC, Delay Request, Follow-up, and Delay Response messages. Figure below shows the method to calculate the propagation delay between nodes supporting peer-to-peer path correction.

**Figure 23-12:** Propagation Delay Calculation between Nodes Supporting Peer-to-Peer Path Correction

As shown in Figure above, the propagation delay is calculated in the following way:

1. Port-1 issues a Pdelay\_Req message and generates a timestamp,  $t_1$ , for the Pdelay\_Req message.
2. Port-2 receives the Pdelay\_Req message and generates a timestamp,  $t_2$ , for this message.
3. Port-2 returns a Pdelay\_Resp message and generates a timestamp,  $t_3$ , for this message. To minimize errors because of any frequency offset between the two ports, Port-2 returns the Pdelay\_Resp message as quickly as possible after the receipt of the Pdelay\_Req message. The Port-2 returns any one of the following:
  - The difference between the timestamps  $t_2$  and  $t_3$  in the Pdelay\_Resp message.
  - The difference between the timestamps  $t_2$  and  $t_3$  in the Pdelay\_Resp\_Follow\_Up message.
  - The timestamps  $t_2$  and  $t_3$  in the Pdelay\_Resp and Pdelay\_Resp\_Follow\_Up messages respectively.
4. Port-1 generates a timestamp,  $t_4$ , on receiving the Pdelay\_Resp message.

Port-1 uses all four timestamps to compute the mean link delay.

## Block Diagram

The following figure shows the functional Block diagram of PTP module.

**Figure 23-13:** PTP Block Diagram

A System Time module is present which keeps the time of PTP module. It consists of hardware which can be programmed by the user for time initialization, time correction and clock correction.

The Timestamp module is capable of capturing the time (provided by System Time module) at various conditions such as, a frame is sent or received by EMAC, rising edge at Auxiliary Snapshot Trigger pin. When System Time is captured after detection of a frame, Timestamp module automatically includes the time information in the frame descriptor. Timestamp on detection on frame can be programmed on per frame basis. Timestamp module also captures the System Time when a rising edge occurs on Auxiliary Snapshot Trigger pin.

PTP module is driven by PTP clock. This clock can be chosen between 3 different clock sources.

Pulse per Second (PPS) module is used to generate a pulse or train of pulse on PPS Output pin, and it is the physical representation of System Time. PPS can be fixed (where only frequency can be varied) or flexible (where width, interval, start time and stop time can be programmed).

Target Time module acts as an Alarm for PTP module. Whenever System Time reaches value equal to programmed Target Time, Target Time trigger interrupt is generated. By appropriate programming, Target Time trigger can also be used to Start or Stop flexible PPS output at specific time.

## PTP Module Clock

The PTP module clock features include *PTP Clock Source Selection* and *PTP Clock Frequency Range*.

### PTP Clock Source Selection

The PTP module can take one of three clock sources as its input clock — SCLK0, RMII Clock or PTP external clock.

PTP clock source can be selected using EMACx field in PADS0\_EMAC\_PTP\_CLKSEL register, as shown in Table below.

| EMACx field | PTP clock source   | Clock Description                  |
|-------------|--------------------|------------------------------------|
| 00          | EMACx_RMII         | RMII reference clock               |
| 10          | PTP External Clock | Clock available on PTP_EXT_CLK pin |
| X1          | SCLK0              | Processor System Clock 0           |

### PTP Clock Frequency Range

The resolution, or granularity, of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance. The maximum PTP clock frequency is limited by the timing constraints achievable for logic operating on the PTP clock. The maximum PTP clock frequency for different PTP clock source is as given below.

| PTP clock source | Maximum PTP clock frequency (MHz) |
|------------------|-----------------------------------|
| SCLK0            | 125                               |
| RMII             | 50                                |
| PTP_EXTCLK       | 83                                |

The minimum PTP clock frequency depends on the time required between two consecutive frames. Because the RMII clock frequency is fixed by IEEE specification, the minimum PTP clock frequency required for proper operation depends upon the operating mode and operating speed of the MAC as shown in Table below.

A minimum delay required between two consecutive timestamp captures is 8 clock cycles of RMII and 3 clock cycles of PTP clocks. If the delay between two timestamp captures is less than this delay, the EMAC does not take a timestamp snapshot for the second frame.

| Mode                           | Minimum Gap Between Two frames                                                                     | Minimum PTP Frequency                                                                                                                                                                                 |
|--------------------------------|----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 100-Mbps full-duplex operation | 336 RMII clocks<br>(256 clocks for a 64-byte frame + 48 clocks of min IFG + 32 clocks of preamble) | $(3 * \text{PTP period}) + (8 * \text{RMII period}) \leq (336 * \text{RMII period})$<br>Maximum PTP period = $(336 - 8) * 20 \text{ ns} \div 3 = 2,186 \text{ ns}$<br>Minimum PTP frequency = 0.46MHz |

## Timestamp Module

Timestamp module captures time in seconds and nanoseconds maintained as System Time. Timestamp module captures time when specific events occur. Events include detection of a frame transmitted or received over EMAC and rising edge on Auxiliary Snapshot Trigger pin. Timestamp module need not timestamp all the frames sent or received over EMAC. PTP module can be programmed to detect specific kinds of frames for timestamping.

## Frame Detection and Timestamping

The PTP module automatically monitors all received and transmitted IEEE 1588 event messages on the Ethernet. If an event message is detected, the module takes a snapshot of the System Time and stores its value to the 64-bit fields in Transmit or Receive Descriptor. The timestamping is done at the EMAC RMII interface when the module sees the start of frame of an event message packet.

## Transmit Path Timestamping

EMAC captures a timestamp when a frame is being sent on RMII. Timestamp capture is controllable on a per-frame basis. In other words, each transmit frame can be marked to indicate whether a timestamp should be captured for that frame or not.

Application should extend the descriptor word length from 4 WORDS to 8 WORDS by setting ATDS (bit7) in EMACx\_DMA\_BUSMODE register. In order to enable Timestamping functionality TTSE (Transmit Timestamp Enable) bit in Transmit Descriptor Word TDES0 should be set. When PTP module captures a Timestamp of a transmitted frame, it is notified to the application by setting the TTSS (Transmit Timestamp Status) in TDES0. The EMAC returns the timestamp to the software inside the corresponding transmit descriptor, thus connecting the timestamp automatically to the specific frame. The 64-bit timestamp information is written to the TDES6 and TDES7 fields. The TDES6 field holds the 32 least significant bits of the timestamp (System Time Nanoseconds), except as described in Transmit Timestamp Field and TDES7 field holds 32 most significant bits (System Time Seconds). After PTP module timestamps the frame, the application can get the timestamp along with the Transmit status from EMAC.

Note: PTP module will timestamp all the transmitting frames that has TTSE set in its TDES0. It will not distinguish according to type of transmitting frame.

## Receive Path Timestamping

PTP module captures the timestamp of received frames on the RMII. Timestamp capture is controllable on a per-frame and per-type basis. In other words each received frame is timestamped according to the frame type.

Applications should extend the descriptor word length from 4 WORDS to 8 WORDS by setting ATDS (bit 7) in EMACx\_DMA\_BUSMODE register, in order to store timestamp and received message status. Receive Time Stamp availability is notified to application when PTP module sets bit 7 (Timestamp Available) in Receive Descriptor Word RDES0. When bit 0 (Extended Status Available) is set in RDES0, it indicates that extended status of PTP frame is provided in RDES4 word. Extended status include PTP Version, PTP Frame Type and Message Type. EMAC returns the timestamp to the software inside the corresponding receive descriptor. The 64-bit timestamp information is written back to the RDES6 and RDES7 fields. The RDES6 holds the 32 least significant bits of the timestamp (System Time Nanoseconds), except as mentioned in Receive Timestamp Field and RDES7 field holds 32 most significant bits (System Time Seconds).

The timestamp is written only to that receive descriptor for which the Last Descriptor status field has been set to 1. When the timestamp is not available (for example, because of an RxFIFO overflow), an all-ones pattern is written to the descriptors (RDES6 and RDES7), indicating that timestamp is not correct. RDES0 [7] will indicate whether the time-stamp is updated in RDES6/7 or not.

Processing of received frames to identify valid PTP frames is done by PTP module. The snapshot of the time to be sent to the application can be controlled using EMACx\_TM\_CTL register.

The PTP module can be programmed to detect all received frames or only some types of PTP frames, according to fields present in EMACx\_TM\_CTL register. Refer to the table given below:

| TSENALL(bit 8) | SNAPTYPSEL(bits [17:16]) | TSMSTRENA(bit 15) | TSEVNTENA(bit 14) | Frames                                 |
|----------------|--------------------------|-------------------|-------------------|----------------------------------------|
| 1              | X                        | X                 | X                 | All                                    |
| 0              | 00                       | X                 | 0                 | Sync, Follow_Up, Delay_Req, Delay_Resp |
| 0              | 00                       | 0                 | 1                 | Sync                                   |
| 0              | 00                       | 1                 | 1                 | Delay_Req                              |

|   |    |   |   |                                                                                                       |
|---|----|---|---|-------------------------------------------------------------------------------------------------------|
| 0 | 01 | X | 0 | Sync, Follow_Up,<br>Delay_Req,<br>Delay_Resp,<br>Pdelay_Req,<br>Pdelay_Resp,<br>Pdelay_Resp_Follow_Up |
| 0 | 01 | 0 | 1 | Sync, Pdelay_Req,<br>Pdelay_Resp                                                                      |
| 0 | 01 | 1 | 1 | Delay_Req,<br>Pdelay_Req,<br>Pdelay_Resp                                                              |
| 0 | 10 | X | X | Sync, Delay_Req                                                                                       |
| 0 | 11 | X | X | Pdelay_Req,<br>Pdelay_Resp                                                                            |

## PTP Processing and Control

When EMAC receives a frame, Frame detection and Timestamping by Timestamp module of PTP is done on the basis of some of the PTP fields in the frame. *PTP Message Format defined in IEEE 1588-2008* shows the common message header for the PTP messages. This format is taken from IEEE standard 1588-2008. When EMAC needs to send a PTP frame, the frame has to follow this format.

When a frame is received, PTP module compares these fields with standard values and finds out the type of PTP frame and other information such as PTP version, IP version, etc. It then updates the related fields in RDES4. When a frame is transmitted user should make sure that all the fields are appropriate such that a PTP module on the other end of communication can correctly detect and decode the frame.

**Table 23-32:** PTP Message Format defined in IEEE 1588-2008

| Bits              |   |   |   |             |   |   |   | Octets | Offset |
|-------------------|---|---|---|-------------|---|---|---|--------|--------|
| 7                 | 6 | 5 | 4 | 3           | 2 | 1 | 0 |        |        |
| transportSpecific |   |   |   | messageType |   |   |   | 1      | 0      |
| Reserved          |   |   |   | versionPTP  |   |   |   | 1      | 1      |
| messageLength     |   |   |   |             |   |   |   | 2      | 2      |
| domainNumber      |   |   |   |             |   |   |   | 1      | 4      |

**Table 23-32:** PTP Message Format defined in IEEE 1588-2008 (Continued)

| Bits               | Octets | Offset |
|--------------------|--------|--------|
| Reserved           | 1      | 5      |
| flagField          | 2      | 6      |
| correctionField    | 8      | 8      |
| Reserved           | 4      | 16     |
| sourcePortIdentity | 10     | 20     |
| sequenceId         | 2      | 30     |
| controlField (*)   | 1      | 32     |
| logMessageInterva  | 1      | 33     |

(\*) – controlField is used in version 1. For version 2, messageType field will be used for detecting different message types.

There are some fields in the Ethernet payload that user can use to detect the PTP packet type and control the snapshot to be taken. These fields are different for the following PTP frames:

- PTP Frames Over IPv4
- PTP Frames Over IPv6
- PTP Frames Over Ethernet

For any of the above PTP frames, EMAC does not consider the PTP version 1 messages as valid PTP messages when frame consists of Peer delay multicast address as destination address (DA).

## PTP Frame Over IPv4

*IPv4-UDP PTP Frame Fields Required for Control and Status* provides information about the fields that are matched to control snapshot for the PTP packets sent over UDP over IPv4 for IEEE 1588 version 1 and 2. The octet positions for the tagged frames are offset by 4. This is based on IEEE 1588-2008 standards and the message format defined in *PTP Message Format defined in IEEE 1588-2008*.

**Table 23-33:** IPv4-UDP PTP Frame Fields Required for Control and Status

| Field Matched  | Octet Position | Matched Value | Description   |
|----------------|----------------|---------------|---------------|
| MAC Frame type | 12, 13         | 0x0800        | IPv4 datagram |

**Table 23-33:** IPv4-UDP PTP Frame Fields Required for Control and Status (Continued)

## PTP Frame Over IPv6

*IPv6-UDP PTP Frame Fields Required for Control and Status* provides information about the fields that are matched to control the snapshots for the PTP packets sent over UDP over IPv6 for IEEE 1588 version 1 and 2. The octet positions for the tagged frames are offset by 4. This is based on IEEE 1588-2008 standards and the message format defined in *PTP Message Format defined in IEEE 1588-2008*.

**Table 23-34:** IPv6-UDP PTP Frame Fields Required for Control and Status

(\*) - The address match of destination address (DA) programmed in MAC address 0 is used if TSENMACADDR (bit 18) in EMACx\_TM\_CTL register is set.

## Auxiliary Timestamp Snapshot

The auxiliary snapshot feature allows storing snapshots of the system time whenever a rising edge is detected on PTP\_AUXIN pin.

PTP stores these snapshots in a 4-deep FIFO. 64-bits of captured timestamp are stored in the FIFO. When a snapshot is stored, PTP indicates this to the EMAC with an interrupt (Auxiliary Snapshot interrupt) and ATSTS (bit 2) in EMACx\_TM\_STMPSTAT register is set. The value of the snapshot is read through EMACx\_TM\_AUXSTMP\_SEC and EMACx\_TM\_AUXSTMP\_NSEC registers. If the FIFO becomes full and an external trigger to take the snapshot is asserted, then a snapshot trigger-missed status (ATSSTM (bit 24)) is set in EMACx\_TM\_STMPSTAT register. The latest snapshot is not written to the FIFO when it is full.

When a host reads the 64-bit timestamp from the FIFO through EMACx\_TM\_AUXSTMP\_SEC and EMACx\_TM\_AUXSTMP\_NSEC registers, the space becomes available to store the next snapshot.

**NOTE:** A space in the FIFO is created whenever EMACx\_TM\_AUXSTMP\_SEC register is read. Hence EMACx\_TM\_AUXSTMP\_NSEC register should be read before reading EMACx\_TM\_AUXSTMP\_SEC register.

User can clear the FIFO by setting the ATSFC (bit 24) in EMACx\_TM\_CTL register. When multiple snapshots are present in the FIFO, the count is indicated in ATSNS (bits [27:25]) of EMACx\_TM\_STMPSTAT register.

**NOTE:** The minimum gap between two events on PTP\_AUXIN must be (4 cycles of PTP\_CLK + 3 cycles of SCLK0). Otherwise, the rising-edge of the trigger is missed by the logic.

## System Time

To get a snapshot of the time, the EMAC requires a reference time in 64-bit format as defined in the IEEE 1588 specification. PTP module maintains 80-bit time, known as System Time and it is updated using the PTP clock.

The 80-bit timing reference is split into the following three registers:

- 32 bit Nanoseconds (EMACx\_TM\_NSEC) register which provides time in nanoseconds
- 32 bit Seconds (EMACx\_TM\_SEC) register which provides time in seconds
- 16 bit High Seconds (EMACx\_TM\_HISEC) register which provides time beyond Seconds register. This register is not included in IEEE 1588 standard, and its use is application specific.

64-bit System Time (Seconds and Nanoseconds) is the source for taking timestamps for Ethernet frames being transmitted or received at the RMII.

Since the PTP clock frequency does not correspond to 1ns period, Nanoseconds register should be incremented with a value equal to PTP clock period for every PTP clock. This is achieved by use of EMACx\_TM\_SUBSEC register. Nanoseconds is incremented with value programmed in EMACx\_TM\_SUBSEC register every PTP clock.

Whenever EMACx\_TM\_SEC register overflow from 0xFFFFFFFF to 0x00000000, Seconds overflow interrupt is triggered and indicated by TSSOVF (bit0) in EMACx\_TM\_STMPSTAT register. After Seconds overflow EMACx\_TM\_HISEC register increments by one.

System Time module supports two types of rollover modes for EMACx\_TM\_NSEC register, Digital rollover and Binary rollover. In digital rollover mode, the maximum value in the nanoseconds field is 0x3B9AC9FF, that is,  $10^9$  nanoseconds. After it reaches this value EMACx\_TM\_SEC register is incremented and EMACx\_TM\_NSEC register restarts count from zero. In binary rollover mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFFFFFF. Accuracy in binary rollover mode is ~0.466 ns per bit, whereas in digital rollover mode it is 1ns per bit.

## System Time Adjustment

The following sections describe the process for system time adjustment.

### System Time Initialization

The System Time can be initialized with 64-bit time when the PTP module is enabled. The initial value is written to the EMACx\_TM\_SECUPDT and EMACx\_TM\_NSECUPDT registers. The System Time counter is written with the value in the System Time Update registers when TSINIT (bit 2) in EMACx\_TM\_CTL register is set.

### Coarse Correction Method

If slave System Time has an offset with respect to the master's System Time, then it can be corrected using Coarse Correction Method. The time offset value is written to the EMACx\_TM\_SECUPDT and EMACx\_TM\_NSECUPDT registers. The offset value is then added to or subtracted from the System Time when TSUPDT (bit 3) in EMACx\_TM\_CTL register is set. Addition or Subtraction can be chosen by using ADDSUB (bit 31) in EMACx\_TM\_NSECUPDT register. System time correction is done in one clock in Coarse Correction Method.

### Fine Correction Method

If slave PTP clock's frequency has a drift with respect to the master PTP clock (as defined in IEEE 1588), then it can be corrected using Fine Correction Method. Here System Time is corrected over a period of time unlike as in Coarse Correction Method where it is done in one clock. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the EMACx\_TM\_ADDEND register, as shown in figure below. The arithmetic carry that the accumulator generates is used as a pulse to increment

the System Time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high-precision frequency divider.

This algorithm for Fine Correction Method is depicted in figure below.

**Figure 23-14:** System Time update using Fine Correction Method

### Example for Calculation of Addend Value

Let the Master clock be 50MHz and the Slave clock be drifted to 66MHz. The aim is to run Slave System Time at 50MHz, so that Slave PTP module is synchronized with Master. If we consider the above diagram, Nanoseconds Increment signal should run at 50MHz. Nanoseconds Increment is the carry from Accumulator register, which is incremented by Addend value at rate of Slave clock (66MHz).

Say Accumulator overflows and generates carry every N Addend values. Hence,  $N * \text{Addend} = 2^{32}$ .

Accumulator is incrementing at 66MHz and carry need to be generated at 50MHz.

Hence,  $N = 66/50 = 1.32$ .

Hence  $\text{Addend} = 2^{32}/1.32 = 0xC1F07C1F$ .

Therefore, if Addend is programmed with 0xC1F07C1F, Slave System Time runs on 50MHz which is synchronized with Master.

In the figure above, the Sub Second Increment is the value which increments Nanoseconds Register according to the frequency of Nanoseconds Increment signal. Sub Second Increment is the value programmed in `EMACx_TM_SUBSEC` register. In the above example, Sub Second Increment should be 20 (for Digital Rollover) or 43 (for Binary Rollover). This will increment `EMACx_TM_NSEC` register by 20ns (1/50MHz).

The software must calculate the drift in frequency and update the `EMACx_TM_ADDEND` register accordingly.

Note: The PTP Reference clock mentioned in the following sections is the clock at which the system time gets updated. When the `TSCFUPDT` (bit 1) of `EMACx_TM_CTL` register is set to 0, this clock is same as the PTP clock. In the Fine Correction mode, PTP reference clock is the clock generated on Nanoseconds Increment signal, at which the system time gets updated.

## Target Time Trigger (Alarm)

The PTP module provides alarm functionality by triggering an alarm at a preset time. It sets `TSTARGET` (bit 1) in the `EMACx_TM_STMPSTAT` register when the System Time matches the value of the `EMACx_TM_TGTM` and `EMACx_TM_NTGTM` registers. This trigger can be used to generate an interrupt and/or command the Flexible PPS module to start/stop PPS output, depending on value programmed in `TRGTMODSEL` (bits [6:5]) in `EMACx_TM_PPSCTL` register. The trigger is enabled by setting `TSTRIG` (bit 4) in `EMACx_TM_CTL` register. Once an alarm has occurred, if another alarm is needed, the software must clear the status bit, reprogram the `EMACx_TM_TGTM` and `EMACx_TM_NTGTM` registers to a future value and set `TSTRIG` (bit 4) in `EMACx_TM_CTL` register.

If the time programmed in Target Time registers is already elapsed, then Target Time programming error is indicated by setting `TSTRGTERR` (bit 3) in `EMACx_TM_STMPSTAT` register.

The alarm time is represented in absolute units, not relative units. For example, if the software needs to generate an alarm after 10 seconds, it must read the current System Time value, add the number corresponding to 10 seconds, and write the result back to the Target Time registers.

## Pulse-Per-Second (PPS)

Pulse-per-second (PPS) is a physical representation of System Time. It is composed of a single pulse or train of pulses. PPS can be used for additional synchronization method or to monitor the synchronization performance between clocks. With proper configuration, the PTP module can be programmed to generate PPS signal which will be output on PTPxPPS pin. PTP supports two kinds of PPS Output, Fixed PPS and Flexible PPS.

## Fixed Pulse-Per-Second Output

EMAC supports fixed pulse-per-second (PPS) output that is given to indicate 1 second interval (default). The frequency of the PPS output can be changed by configuring PPSCTL (bits[3:0]) in EMACx\_TM\_PPSCTL register. The default value of PPSCTL is 0000, for which the PPS output is 1Hz signal with pulse width equals period of PTP clock.

The table below shows various frequencies achievable on PPS Output by varying PPSCTL.

| PPSCTL | Binary Rollover | Digital Rollover |
|--------|-----------------|------------------|
| 0001   | 2 Hz            | 1 Hz             |
| 0010   | 4 Hz            | 2 Hz             |
| 0011   | 8 Hz            | 4 Hz             |
| ...    | ...             | ...              |
| 1111   | 32.768 KHz      | 16.384 KHz       |

In the binary rollover mode, the PPS output has a duty cycle of 50 percent with these frequencies.

In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. PPS output pulses will have different period and duty cycle and this behavior is because of the non-linear toggling of the bits in the digital rollover mode. For example:

- When PPSCTL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms.
- When PPSCTL = 0010, the PPS (2 Hz) is a sequence of: - One clock of 50 percent duty cycle and 537 ms period - Second clock of 463 ms period (268 ms low and 195 ms high).
- When PPSCTL = 0011, the PPS (4 Hz) is a sequence of: - Three clocks of 50 percent duty cycle and 268 ms period - Fourth clock of 195 ms period (134 ms low and 61 ms high).

## Flexible Pulse-Per-Second Output

EMAC also provides the flexibility to program the start or stop time, width, and interval of the pulse generated on the PPS output. This feature is called Flexible PPS and can be enabled by setting PPSSEN (bit 4) in EMACx\_TM\_PPSCTL register.

EMAC provides the following features with the Flexible PPS output option:

- Supports programming the start point of the single pulse and start and stop points of the pulse train in terms of System Time. The existing Target Time registers are used to program the start and stop time.
- Supports programming the stop time in advance, that is, user can program the stop time before the actual start time has elapsed.

- Supports programming the width, between the rising edge and corresponding falling edge of PPS signal output, in terms of number of units of sub-second increment value programmed in EMACx\_TM\_SUBSEC register.
- Supports programming the interval, between the rising edges of PPS signal, in terms of number of units of sub-second increment value programmed in EMACx\_TM\_SUBSEC register.
- Provides the option to cancel the programmed PPS start or stop request.
- Indicates error if the start or stop time being programmed has already elapsed.

### PPS Start or Stop Time

Start time can be initially programmed in the Target Time registers. If required, the start or stop time can be programmed again but it can be done only after the earlier programmed value is synchronized to the PTP clock domain. TSTRBUSY (bit 31) of EMACx\_TM\_NTGMT register indicates the status of synchronization. This enables user to program the start or stop time in advance, even before the earlier stop or start time has elapsed.

The start or stop time should be programmed with advanced system time to ensure proper PPS signal output. If the application programs a start or stop time that has already elapsed, then the EMAC sets TSTRGTERR (bit 3) in EMACx\_TM\_STMPSTAT register indicating the programming error. If enabled, the EMAC also sets the Target Time trigger (Alarm) interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

### PPS Width and Interval

The PPS width and interval are programmed in terms of granularity of system time, that is, number of the units of sub-second increment value. For example, to have a PPS pulse width of 40ns and interval of 100ns, with the PTP reference clock of 50MHz, the width and interval should be programmed to values 2 and 5 respectively. Smaller granularity can be achieved by using a faster PTP reference clock. Before giving the command to trigger a pulse or pulse train on the PPS output, user should program or update the interval and width of the PPS signal output.

### PPS Command

When the PPS module is configured for Flexible PPS output, the PPSCTL (bits[3:0]) field in EMACx\_TM\_PPSCTL register can be used to command the PPS module for utilizing any of the Flexible PPS features.

Programming these bits with a non-zero value instructs the PPS module to initiate an event. Once the command is transferred or synchronized to the PTP clock domain, these bits gets cleared automatically. Software should ensure that these bits are programmed only when they are “all-zero”.

Table below explains the different commands available and their functionality.

| PPSCTL (bits [3:0]) | Command                      | Description                                                                                                                                                                                                                                                                                                                                                          |
|---------------------|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0000                | No Command                   |                                                                                                                                                                                                                                                                                                                                                                      |
| 0001                | Start Single Pulse           | Generates single pulse rising at start point defined in Target Time registers and of duration defined in EMACx_TM_PPSWIDTH register.                                                                                                                                                                                                                                 |
| 0010                | Start Pulse train            | Generates train of pulses rising at the Start Time configured in the Target Time registers, of duration configured in the EMACx_TM_PPSWIDTH register and repeated at interval configured in the EMACx_TM_PPSINTVL register. By default, the PPS pulse train is free-running unless stopped by 'Stop Pulse train at time' or 'Stop Pulse train immediately' commands. |
| 0011                | Cancel Start                 | Cancels the 'Start Single Pulse' and 'Start Pulse train' commands if the system time has not crossed the programmed start time.                                                                                                                                                                                                                                      |
| 0100                | Stop Pulse train at time     | Stops the train of pulses initiated by the 'Start Pulse train' command after the time programmed in the Target Time registers elapses.                                                                                                                                                                                                                               |
| 0101                | Stop Pulse train immediately | Immediately stops the train of pulses initiated by the 'Start Pulse train' command.                                                                                                                                                                                                                                                                                  |
| 0110                | Cancel Stop Pulse train      | Cancels the 'Stop Pulse train at time' command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command.                                                                                                                                                                                    |
| 0111-1111           | Reserved                     |                                                                                                                                                                                                                                                                                                                                                                      |

### Interrupts related to PTP

Interrupts from PTP module can be enabled by setting TS (bit 9) in EMACx\_IMSK register. The status of the interrupt is indicated on TS (bit 9) of EMACx\_ISTAT register. PTP supports three types of interrupts.

### Auxiliary Snapshot Trigger

This interrupt is triggered when an external event occurs on PTP\_AUX\_IN pin and timestamp snapshot occurs. This is indicated on bit2 of EMACx\_TM\_STMPSTAT register.

### Target Time Reached

This interrupt is triggered when the System Time becomes equal to the value written in EMACx\_TM\_TGTM and EMACx\_TM\_NTGTM registers. It can be enabled or disabled by using TSTRIG (bit4) in EMACx\_TM\_CTL register and TRGTMODESEL (bit [6:5]) in EMACx\_TM\_PPSCTL register. This interrupt can be used as Alarm. This interrupt is indicated on TSTARGET (bit1) of EMACx\_TM\_STMPSTAT register.

## System Time Seconds Register Overflow

This interrupt is triggered when the EMACx\_TM\_SEC register overflows from 0xFFFF FFFF to 0x0000 0000. This interrupt is indicated on TSSOVF(bit 0) of EMACx\_TM\_STMPSTAT register. As soon as EMACx\_TM\_SEC register overflows, EMACx\_TM\_HISEC register increments by one.

## EMAC Event Control

The EMAC has a dedicated interrupt signal registered with the Processor System Event Controller. Various interrupt sources within EMAC peripheral are shared through this interrupt line. Please refer to the System Event Controller chapter for details on how interrupts work in BF60x and how to configure the same.

## EMAC Interrupt Signals

Interrupts from the EMAC can be triggered from the EMAC DMA layer or the EMAC CORE layer. Interrupts are triggered from EMAC DMA if a particular status bit is set in DMA status register. An interrupt line is asserted only when the corresponding bits are enabled in the DMA interrupt enable register. Similarly, interrupts are triggered from the EMAC CORE if a particular MMC status bit or PTP status bit is set in the interrupt status register. An interrupt line is asserted only when the corresponding bits are enabled in the MMC mask registers in case of MMC counters or the interrupt mask register in the case of PTP. Note that MMC interrupt status is also reflected in the DMA status register. The two groups of interrupts in the DMA status register are listed below.

NIS – Normal Interrupt source summary.

- Transmit Interrupt.
- Transmit Buffer Unavailable.
- Receive Interrupt.
- Early Receive Interrupt.

AIS – Abnormal Interrupt source summary.

- Transmit Process Stopped.
- Transmit Jabber Timeout.
- Receive FIFO Overflow.
- Transmit Underflow.
- Receive Buffer Unavailable.

- Receive Process Stopped.
- Receive Watchdog Timeout.
- Early Transmit Interrupt.
- Fatal Bus Error.

An interrupt is generated only once for simultaneous, multiple events. The driver must read the DMA Status Register for the cause of the interrupt. The interrupt is not generated again unless a new interrupting event occurs, after the driver has cleared the appropriate bit in DMA status register. For example, the controller generates a Receive interrupt (bit 6 of DMA status register) and the driver begins reading DMA Status Register. Next, Receive Buffer Unavailable (bit 7 of DMA status register) occurs. The driver clears the Receive interrupt. Even then, the internal interrupt signal is not de-asserted, because of the active or pending receive buffer unavailable interrupt. Additionally, the driver must scan all descriptors, from the last recorded position to the first one owned by the DMA, in order to know which descriptor has asserted the interrupt.

Interrupts are cleared by writing a 1 to the corresponding bit position in the DMA status register. When all the enabled interrupts within a group are cleared, the corresponding summary bit is cleared.

An interrupt delay timer is provided (receive interrupt watchdog timer register) is provided for flexible control of Receive Interrupt. When this Interrupt timer is programmed with a non-zero value, it gets activated as soon as the RxDMA completes a transfer of a received frame to system memory without asserting the Receive Interrupt because it is not enabled in the corresponding receive descriptor (RDES1[31] in Receive DMA descriptors). When this timer runs out (per the programmed value), the **RI** bit is set and the interrupt is asserted if the corresponding **RI** is enabled in the interrupt enable register. This timer is disabled before it runs out, when a frame is transferred to memory and **RI** is set because it is enabled for that descriptor.

**Figure 23-15: EMAC Interrupt Flow Diagram**

## PHYINT Interrupt Signal

PHY device can notify the Blackfin EMAC when it detects changes to the link status, such as auto-negotiation or duplex-mode change. The external PHY chip typically includes an interrupt generation pin, in order to aid this status change notification to the MAC. This signal is typically termed as PHYINT and a falling/rising edge on this signal can be used to detect as a PHY interrupt at the EMAC.

In BF60x, any of the GPIO pin can be a PHYINT. In order to use the PHYINT, user may follow the below sequence:

1. Program the GPIO to detect a falling/rising edge sensitive interrupt.
2. Program the PHY to generate the Interrupt upon status change.
3. If PHYINT is asserted, read the PHY Status register via Station Management Interface.

**NOTE:** The PHYINT is not part of EMAC module, but rather any GPIO pin can be configured to interrupt the processor, upon detecting a rising edge generated by PHY.

Please refer to GPIO Chapter for more info on configuring GPIO pins for input.

## EMAC Programming Model

This section provides the programming model of Ethernet MAC peripheral for developers.

## EMAC Programming Steps

The following sections provide some general programming information

### DMA Initialization

1. Provide software reset by setting `SWR` bit in DMA Bus Mode Register (`DMA_BUSMODE`). This resets all of the EMAC internal registers and logic.
2. Wait for the completion of the reset process by polling `SWR` bit of the DMA Bus Mode Register (`DMA_BUSMODE`), which is only cleared (automatically) after the reset operation is completed.
3. Poll the `BUSRD` and `BUSWR` bits of the SCB Status Register (`DMA_BMSTAT`) to confirm that all previously initiated (before software-reset) or ongoing SCB transactions are complete.
4. Program the required fields in the DMA Bus Mode Register (`DMA_BUSMODE`):
  - a. Address Aligned Bursts.
  - b. Fixed burst or undefined burst.
  - c. Burst length values and burst mode values.
  - d. Descriptor Length (only valid if Ring Mode is used).
5. Program the SCB interface options in Bus Mode Register (`DMA_BMMODE`). If fixed burst-length is enabled, then select the maximum burst-length possible on the SCB bus (bits `BLN4`, `BLN8`, `BLN16`).
6. Create a proper descriptor chain for transmit and receive. In addition, ensure that the receive descriptors are owned by DMA (`OWN` bit of descriptor should be set). When `OSF` mode is used, at least two descriptors are required.
7. Make sure that your software creates three or more different transmit or receive descriptors in the chain before reusing any of the descriptors.

8. Initialize Receive Descriptor List Address Register (DMA\_RXDSC\_ADDR) and Transmit Descriptor List Address Register (DMA\_TXDSC\_ADDR) with the base address of receive and transmit descriptor respectively.
9. Program the required fields to initialize the mode of operation in Operation Mode Register (DMA\_OPMODE):
  - a. Receive and Transmit Store and Forward.
  - b. Receive and Transmit Threshold Control (RTC and TTC).
  - c. Error Frame and undersized good frame forwarding enable.
  - d. OSF Mode.
10. Clear the interrupt requests, by writing to those bits of the status register (interrupt bits only) that are set. For example, by writing 1 into bit 16, the normal interrupt summary clears this bit DMA Status Register (DMA\_STAT).
11. Enable the interrupts by programming the Interrupt Enable Register (DMA\_IEN).
12. Start the Receive and Transmit DMA by setting SR (bit 1) and ST (bit 13) of the DMA Operation Mode Register (DMA\_OPMODE).

## **EMAC CORE Initialization**

1. Program the EMAC Management Address Register (SMI\_ADDR) for controlling the management cycles for external PHY. For example, Physical Layer Address (bits 15-11). In addition, set bit 0 (SMI Busy) for writing into PHY and reading from PHY.
2. Read the 16-bit data of Management Data Register (SMI\_DATA) from the PHY for link up, speed of operation, and mode of operation, by specifying the appropriate address value in bits 15-11 of Management Address Register (SMI\_ADDR).
3. Program the MAC address in to EMAC Address0 High Register (ADDR0\_HI) and EMAC Address0 Low Register (ADDR0\_LO).
4. If Hash filtering is used, program Hash Table High Register (HASHTBL\_HI) and Hash Table Low Register (HASHTBL\_LO).

5. Program the required fields to set the appropriate filters for the incoming frames in MAC Frame Filter Register (MACFRMFILT):
  - a. Receive All.
  - b. Promiscuous mode.
  - c. Hash or Perfect Filter.
  - d. Unicast, multicast, broadcast, and control frames filter settings.
6. Program the required fields for proper flow control in Flow Control Register (FLOWCTL):
  - a. Pause time and other pause frame control bits.
  - b. Receive and Transmit Flow control bits.
  - c. Flow Control Busy/Backpressure Activate.
7. Program the EMAC Interrupt Mask Register bits (IMSK), as required.
8. Program the appropriate fields in MAC Configuration Register (MACCFG). For example, Inter-frame gap while transmission and jabber disable. Based on the Auto-negotiation you can set the Duplex mode (bit 11) or speed select (bit 14).
9. Set the bits Transmit enable (TE bit-3) and Receive Enable (RE bit-2) in MAC Configuration Register (MACCFG).

## Performing Normal Transmit and Receive Operations

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the application (either transmit or receive).
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and issuing a poll demand by writing 0 into the Tx/Rx poll demand register (DMA\_TXPOLL and DMA\_RXPOLL).
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process via Current Host Transmit Descriptor Register (DMA\_TXDSC\_CUR) and Current Host Receive Descriptor Register (DMA\_RXDSC\_CUR).
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process via Current Host Transmit Buffer Address Register (DMA\_TXBUF\_CUR) and Current Host Receive Buffer Address Register (DMA\_RXBUF\_CUR).

## Stopping and Starting Transfers

1. Disable the Transmit DMA (if applicable), by clearing bit 13 (ST: Start/Stop Transmission Command) of DMA Operation Mode Register (DMA\_OPMODE).
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of EMAC Debug Register (DBG).
3. Disable the MAC transmitter and MAC receiver by clearing the bit 3 (TE: Transmitter Enable) and bit 2 (RE: Receiver Enable) in MAC Configuration Register (MACCFG).
4. Disable the Receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory by reading EMAC Debug Register (DBG).
5. Make sure that both Tx FIFO and Rx FIFO are empty.
6. To re-start the operation, first start the DMAs, and then enable the MAC Transmitter and Receiver.

## EMAC Interrupts and ISRs

Specific steps for enabling interrupts and using their ISRs are outlined here.

*PREREQUISITE:* This may typically be assumed on top of steps for EMAC and DMA initialization and operations.

1. Receive interrupts are enabled for descriptors by default. Transmit interrupts must be enabled for individual descriptors by setting bit IC (bit 30) in TDES0 word of transmit descriptor.
2. Enable required bits in DMA Interrupt Enable register DMA\_IEN. Setting AIE or NIE can turn on the occurrence of all normal / abnormal interrupt conditions. Different conditions may also be turned on directly by setting individual bits in DMA\_IEN register.
3. MMC overflow interrupts are enabled by setting appropriate bits in MMC\_TXIMSK and MMC\_RXIMSK registers.
4. PTP interrupts are enabled by setting TS bit in EMACx\_IMSK register.

5. Once EMAC interrupt is asserted and SEC branches execution to EMAC ISR, below sequence may be followed in software:
  - a. Read DMA status from `DMA_STAT` register.
  - b. Clear interrupt source by writing 1 in to the bits that are set in `DMA_STAT` (W1C).
  - c. Check for normal / abnormal / mmc / ptp interrupt by parsing status bits in DMA status value read earlier, and call appropriate service function.
  - d. Typical normal interrupt assertions include Transmit and Receive Interrupt.
  - e. Typical abnormal interrupt assertion include Receive Underflow.
6. MMC handler functions may follow the below sequence:
  - a. First read whether it is Transmit Counter Interrupt or Receive Counter Interrupt, by reading `ISTAT` register and parsing for `MMCTX` and `MMCRX` bits respectively.
  - b. Read `MMC_RXINT` or `MMC_TXINT` registers to check for which of the counters have triggered interrupt.
  - c. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read.
7. PTP handler functions may follow the below sequence:
  - a. First read whether it is PTP Interrupt, by reading `ISTAT` register and parsing for `TS` bit.
  - b. Read `TM_STMPSTAT` register and determine interrupt source by parsing `ATSTS`, `TSTARGT` and `TSSOVF` bits.
  - c. Interrupt source is cleared by reading `TM_STMPSTAT` register.

## Enabling Checksum for Transmit and Receive

Specific steps for enabling transmit and receive checksum are outlined here.

### *PREREQUISITE:*

This may typically be assumed on top of steps for EMAC and DMA initialization and operations. Note that transmit and receive checksum features are independent of each other.

1. To enable Transmit Checksum Insertion:
  - a. Enable Store Forward mode in FIFO (set `TSF` bit in `OPMODE` register).
  - b. Make sure that the transmit frame can be contained within the TX FIFO of 256 bytes confirming to the size rule:  $\text{FIFO Depth} - \text{PBL} - 3 \text{ FIFO Locations}$ , where PBL is Burst Length.
  - c. Program required option for transmit checksum, by programming (CIC) Checksum Insertion Control in Transmit Descriptor Word 0 (TDES0): IP header checksum / IP header checksum and payload checksum / IP Header checksum, payload checksum and pseudo header checksum.
  - d. Higher layer such as IP Stack sends out packet to EMAC which inserts checksum as configured above.
2. To enable Receive Checksum Verification:
  - a. Enable Receive Checksum off-load engine (set `IPC` bit in `MACCFG` register).
  - b. Enable 8 word descriptor (32 bytes), by setting `ATDS` bit in DMA Bus Mode register.
  - c. Provide a total of 8 x 32-bit word space for receive descriptor.
  - d. Wait for Receive Interrupt and check for extended status availability by parsing bit 0 in RDES0 word.
  - e. If extended status available, read RDES4 and pass to higher layer such as IP-stack.
  - f. Higher software layer may check for IPv4/IPv6/Payload Type and Checksum Payload/Header errors.

## Programming System Time Module

*PREREQUISITE:* PTP configurations and programming may typically be assumed on top of steps for EMAC and DMA initialization and operations., since PTP is a sub-block in EMAC.

1. Enable PTP module by setting `TSENA` (bit 0) in `EMACx_TM_CTL` register.

## 2. System Time Initialization

- a. The time (seconds and nanoseconds) at which System Time should be initialized should be written into EMACx\_TM\_SECUPDT and EMACx\_TM\_NSECUPDT registers.
- b. Set TSINIT (bit2) in EMACx\_TM\_CTL register. System Time is initialized and TSINIT bit clears automatically.
- c. Binary or Digital rollover of EMACx\_TM\_NSEC register can be chosen by configuring TSCTRLSSR (bit9) in EMACx\_TM\_CTL register.

## 3. System Time Coarse Correction

- a. The Offset time (seconds and nanoseconds) which has to be added or subtracted to System Time, should be written into EMACx\_TM\_SECUPDT and EMACx\_TM\_NSECUPDT registers.
- b. Configure ADDSUB (bit31) of EMACx\_TM\_NSECUPDT register to choose between add or subtract offset time.
- c. Set TSUPDT (bit3) in EMACx\_TM\_CTL register. System Time is corrected with offset time and TSUPDT bit clears automatically.

## 4. System Time Fine Correction

- a. Calculate required Addend value based on input PTP clock frequency and required frequency. Refer to Fine Correction Method section.
- b. Write the calculated Addend value in EMACx\_TM\_ADDEND register and set TSADDREG (bit5) in EMACx\_TM\_CTL register. Addend value is updated and TSADDREG bit is cleared automatically.
- c. Configure EMACx\_TM\_SUBSEC register based on new PTP frequency.

## 5. Target Time trigger (Alarm)

- a. Set TS (bit 9) in EMACx\_IMSK register to enable PTP interrupts.
- b. Program TRGTMODESEL (bits[6:5]) in EMACx\_TM\_PPSCTL register with 00 or 10 (for PPS start/stop time programming).
- c. Program the time when interrupt should be triggered, in the EMACx\_TM\_TGTM and EMACx\_TM\_NTGTM registers. The programmed time should be greater than the current System Time. Else Target time programming error occurs indicated by TSTRGTERR (bit 3) in EMACx\_TM\_STMPSTAT register.
- d. Set TSTRIG (bit 4) in EMACx\_TM\_CTL register to enable Target Time trigger interrupt. After System Time reaches programmed target time (in step 2), Target time trigger interrupt occurs indicated by TSTARGET (bit 1) in EMACx\_TM\_STMPSTAT register and TS (bit 9) in EMACx\_ISTAT register. TSTRIG is cleared automatically.

## Programming PTP module for Frame detection and Timestamping

*PREREQUISITE:* PTP configurations and programming may typically be assumed on top of steps for EMAC and DMA initialization and operations., since PTP is a sub-block in EMAC.

1. For timestamping a transmitting frame, TTSE bit in TDES0 of corresponding frame should be set.
2. Extend the descriptor word length from 4 WORDS to 8 WORDS by setting ATDS (bit 7) in EMACx\_DMA\_BUSMODE register.
3. Configure the fields (bit [18:10]) in EMACx\_TM\_CTL register so that PTP module will detect and/or time-stamp only specific types of received frames. Refer to EMACx\_TM\_CTL register description for more information.
4. Select PTP clock source by programming PADS0\_EMAC\_PTP\_CLKSEL register.
5. PTP module should be enabled by setting TSENA (bit 0) in EMACx\_TM\_CTL register.
6. System Time should be initialized.
7. Verify the RDES4 for status of the received frame and RDES6 and RDES7 for Timestamp nanoseconds and seconds value.

## Programming for Auxiliary Timestamps

*PREREQUISITE:* PTP configurations and programming may typically be assumed on top of steps for EMAC and DMA initialization and operations., since PTP is a sub-block in EMAC.

1. Set TS (bit 9) in EMACx\_IMSK register to enable PTP interrupts.
2. PTP module should be enabled by setting TSENA (bit 0) in EMACx\_TM\_CTL register.
3. System Time should be initialized.
4. Whenever a rising edge on Auxiliary Timestamp Trigger pin is detected, System Time seconds and nanoseconds are captured and stored into 4-deep Auxiliary Timestamp FIFO. Auxiliary timestamp trigger interrupt occurs indicated by ATSTS (bit 2) in EMACx\_TM\_STMPSTAT register and TS (bit 9) in EMACx\_ISTAT register.
5. The contents of FIFO can be read one by one through EMACx\_TM\_AUXSTMP\_SEC and EMACx\_TM\_AUXSTMP\_NSEC registers. One level of FIFO is cleared when EMACx\_TM\_AUXSTMP\_SEC register is read. Hence read EMACx\_TM\_AUXSTMP\_NSEC register before EMACx\_TM\_AUXSTMP\_SEC register.
6. FIFO can be cleared by setting ATSFC (bit24) in EMACx\_TM\_CTL register.

## Programming Pulse-Per-Second Output

*PREREQUISITE:* PTP configurations and programming may typically be assumed on top of steps for EMAC and DMA initialization and operations., since PTP is a sub-block in EMAC.

### 1. Fixed Pulse-Per-Second Output

- a. PTP module should be enabled by setting TSENA (bit 0) in EMACx\_TM\_CTL register.
- b. Configure PPSCTL (bits [3:0]) in EMACx\_TM\_PPSCTL register and Binary or Digital rollover by configuring TSCTRLSSR (bit 9) in EMACx\_TM\_CTL register, so as to output required PPS waveform. Refer to Fixed PPS section.

### 2. Flexible Pulse-Per-Second Output

- a. PTP module should be enabled by setting TSENA (bit 0) in EMACx\_TM\_CTL register.
- b. Set PPSEN (bit 4) of EMACx\_TM\_PPSCTL register to enable Flexible PPS output.
- c. Program TRGTMODESEL (bits[6:5]) in EMACx\_TM\_PPSCTL register with 11 or 10 (for Target time trigger interrupt).
- d. Program the start time value when PPS output should start, in the EMACx\_TM\_TGTM and EMACx\_TM\_NTGTM registers. Ensure that TSTRBUSY (bit 31) of EMACx\_TM\_NTGTM register is reset before programming the Target Time registers again.
- e. Program the period of PPS signal output in EMACx\_TM\_PPSINTVL register for Pulse Train output, and width of the PPS signal output in EMACx\_TM\_PPSWIDTH register for Single Pulse or Pulse Train output.
- f. Ensure that PPSCTL (bits [3:0]) of EMACx\_TM\_PPSCTL register is cleared and program PPSCTL to 0001 to start Single Pulse, or program PPSCTL to 0010 to start Pulse Train at programmed start time (step 4). The PPS Pulse Train is free-running unless stopped by 'STOP Pulse train at time Command' (PPSCTL=0100) or 'STOP Pulse Train immediately Command' (PPSCTL=0101).
- g. Start of Pulse generation can be cancelled by giving the 'Cancel Start Command' (PPSCTL=0011) before the programmed start time (step 4) elapses.
- h. Program the stop time value when PPS output should stop, in the EMACx\_TM\_TGTM and EMACx\_TM\_NTGTM registers. Ensure that TSTRBUSY (bit 31) of EMACx\_TM\_NTGTM register is reset before programming the Target Time registers again.
- i. Ensure that PPSCTL (bits [3:0]) of EMACx\_TM\_PPSCTL register is cleared and program PPSCTL to 0100. This stops the train of pulses on PPS signal output after the programmed stop time (step 8) elapses.
- j. Pulse train can be stopped immediately by giving 'STOP Pulse Train immediately Command' (PPSCTL=0101). Similarly, 'Stop Pulse train Command' (given in step 9) can be cancelled by programming 0110 in the PPSCTL field before the programmed stop time (step 8) elapses.

## EMAC Programming Concepts

### IEEE 802.3 Ethernet Packet Structure

Typical frame format of an Ethernet packet is given below. Please refer to IEEE standards for detailed information on Ethernet packets and their format.

**Table 23-36:** IEEE 802.3 frame structure

| Parameter<br>Description (original source: <a href="http://www.wikipedia.com">www.wikipedia.com</a> ).                                                                                                                                                                                                                        | Position in Ethernet<br>packet | Total Bytes |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|-------------|
| <b>PREAMBLE</b><br>The preamble of an Ethernet frame consists of a 56-bit (7-byte) pattern of alternating 1 and 0 bits (#10101010), which allows devices on the network to easily detect a new incoming frame (synchronization purpose).                                                                                      | 1                              | 7           |
| <b>SFD</b><br>The SFD (#10101011) is a 1-byte pattern designed to break the preamble pattern, and signal the start of the actual frame.                                                                                                                                                                                       | 2                              | 1           |
| <b>DA</b><br>48 bits long Destination address. This can be a Unicast, Multicast or Broadcast address.                                                                                                                                                                                                                         | 3                              | 6           |
| <b>SA</b><br>48 bits long Source address. This is typically Unicast, Multicast or Broadcast address.                                                                                                                                                                                                                          | 4                              | 6           |
| <b>LT</b><br>Typically this field is the length in terms of the number of bytes and can be anywhere between 0 – 1500. When the value is greater than or equal to 0x0600, this field is also used to indicate the type of special payload carried by the frame. Examples include: 0x8808 for flow control and 0x0800 for IPv4. | 5                              | 2           |
| <b>DATA</b><br>Actual application data payload; usually between 0 – 1500.                                                                                                                                                                                                                                                     | 6                              | 0 - 1500    |
| <b>PAD</b><br>Frames must be at least 64 bytes long, not including the preamble, so, if the Data field is shorter than 46 bytes, it must be compensated by the Pad field.                                                                                                                                                     | 7                              | 0 - 46      |

**Table 23-36:** IEEE 802.3 frame structure (Continued)

| Parameter<br>Description (original source: www.wikipedia.com).                                                                                                                                                                                                                                                               | Position in Ethernet<br>packet | Total Bytes |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|-------------|
| FCS<br>The frame check sequence is a 32-bit cyclic redundancy check which enables detection of corrupted data within the entire frame. This is generated from a CRC-32 polynomial code (CRC-32-IEEE): $G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$ . | 8                              | 4           |

## Frame Size Statistics for Application Software

**Table 23-37:** Ethernet Frame Size statistics

| Frame size statistics        | VLAN specific change<br>Comments                                                                    |                                                                                   |
|------------------------------|-----------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| Information bytes / Header   | 4 byte 802.1Q header inserted after Source Address and before Type/LAN in 802.3 packets = 22 bytes. | $6 \times 2 + 2 + 4 = 18$ bytes (DA+SA+LT+FCS)                                    |
| Minimum Frame Size (typical) | If DATA is NULL, 42 byte padding is done to make 64 bytes (42 + 22)                                 | 64 bytes. If DATA is NULL, 46 byte padding is done to make 64 bytes (46 + 18)     |
| Maximum Frame Size (typical) | 1522 bytes                                                                                          | 1518 bytes (1500 bytes DATA and 18 bytes header)                                  |
| Jumbo Frame Size             | 9022 bytes                                                                                          | Typical industry standard Ethernet jumbo frame size may be treated as 9018 bytes. |

## Software Visualization of Programmable Packet Size

**Table 23-38:** Visualization of Programmable Packet Size

| Size in bytes | Comments                                                            |
|---------------|---------------------------------------------------------------------|
| 16384         | Receive Watchdog & Transmit Jabber disabled, Jumbo frames enabled.  |
| 10240         | Receive Watchdog & Transmit Jabber disabled, Jumbo frames disabled. |
| 2048          | Receive Watchdog & Transmit Jabber enabled.                         |

**Table 23-38:** Visualization of Programmable Packet Size (Continued)

| Size in bytes | Comments                                                                          |
|---------------|-----------------------------------------------------------------------------------|
| 1518          | Typical max size of Ethernet frame. Receive Watchdog and Transmit Jabber enabled. |
| 64            | Typical min size of Ethernet frame.                                               |
| < 64          | Runt frames requiring Zero-PAD.                                                   |

## Ethernet Packet Structure in C

```
/*Example for Ethernet packet structure in C language*/
typedef struct ETHER_PACKET
{
    char  dst_addr[6];           //destination address
    char  src_addr[6];           //source address
    char  length[2];             //length of actual data
    char  data[DATA_SIZE];       //application data
    char  fdlimit[DELIMIT_SIZE]; //32-bit delimit (if manual appending)
    char  fcs[4];                //crc frame checksum, used by RX buffer.
} ETHER_PACKET;
```

## DMA Descriptor Implementation in C

```
/*
 * Following is a simple implementation of Descriptors in Ring and Chain model in C
 language.
 * Typically 4 WORDs (32-bit) are used for descriptors. Using Checksum offload or PTP
 Engine requires 8 WORDs.
 * Only high-level common functionalities across transmit and receive descriptors are
 considered here.
 */
/* DMA Ring Descriptor */
typedef struct EMAC_DMADESC_RING
{
    unsigned int      Status; //TDES0 OR RDES0
    unsigned int      ControlDesc; //TDES1 OR RDES1
    unsigned int      StartAddr1; //TDES2 OR RDES2
    unsigned int      StartAddr2; //TDES3 OR RDES3
#ifdef CHECKSUM_OFFLOAD
    struct EMAC_EXT_STAT ExtendedStat;
#endif
} EMAC_DMADESC_RING;
/* DMA Chain Descriptor */
typedef struct EMAC_DMADESC_CHAIN
{
    unsigned int      Status; //TDES0 OR RDES0
    unsigned int      ControlDesc; //TDES1 OR RDES1
```

```

        unsigned int                StartAddr; //TDES2 OR RDES2
        struct EMAC_DMADESC_CHAIN *pNextDesc; //TDES3 OR RDES3
#ifdef CHECKSUM_OFFLOAD
        struct EMAC_EXT_STAT ExtendedStat;
#endif
    } EMAC_DMADESC_CHAIN;
/* Extended Status Descriptor with PTP not enabled*/
typedef struct EMAC_EXT_STAT
{
    #ifdef RX_DESC
        unsigned int                CheckSumStat; //RDES4
    #ifdef TX_DESC
        unsigned int                Reserved; //TDES4
    #endif
        unsigned int                Reserved; //RDES5 OR TDES5
        unsigned int                Reserved; //RDES6 OR TDES6
        unsigned int                Reserved; //RDES7 OR TDES7
    } EMAC_EXT_STAT;

```

## PTP Header Structure in C

```

/* PTP Message Format (Refer to Table23-33)*/
typedef struct EMAC_PTP_HEADER
{
    unsigned char messageType:4; //PTP Version 2 message type
    transportSpecific:4;
    unsigned char versionPTP; //PTP Version (1 or 2)
    unsigned short messageLength;
    unsigned char domainNumber;
    unsigned char RESERVED1;
    unsigned short flagField;
    unsigned char correctionField[8];
    unsigned char RESERVED2[4];
    unsigned char sourcePortIdentity[10];
    unsigned short sequenceId;
    unsigned char controlField; //PTP Version 1 message type
    unsigned char logMessageInterval;
} EMAC_PTP_HEADER;

```

## EMAC Register Descriptions

Ethernet MAC (EMAC) contains the following registers.

**Table 23-39:** EMAC Module Registers

| Name        | Description                |
|-------------|----------------------------|
| EMAC_MACCFG | MAC Configuration Register |

**Table 23-39:** EMAC Module Registers (Continued)

| Name              | Description                           |
|-------------------|---------------------------------------|
| EMAC_MACFRMFILT   | MAC Rx Frame Filter Register          |
| EMAC_HASHTBL_HI   | Hash Table High Register              |
| EMAC_HASHTBL_LO   | Hash Table Low Register               |
| EMAC_SMI_ADDR     | SMI Address Register                  |
| EMAC_SMI_DATA     | SMI Data Register                     |
| EMAC_FLOWCTL      | FLow Control Register                 |
| EMAC_VLANTAG      | VLAN Tag Register                     |
| EMAC_DBG          | Debug Register                        |
| EMAC_ISTAT        | Interrupt Status Register             |

| EMAC_DMA_BMSTAT     | DMA SCB Status Register                 |
| EMAC_DMA_TXDSC_CUR  | DMA Tx Descriptor Current Register      |
| EMAC_DMA_RXDSC_CUR  | DMA Rx Descriptor Current Register      |
| EMAC_DMA_TXBUF_CUR  | DMA Tx Buffer Current Register          |
| EMAC_DMA_RXBUF_CUR  | DMA Rx Buffer Current Register          |

## MAC Configuration Register

The EMAC\_MACCFG register configures MAC features.

EMAC\_MACCFG: MAC Configuration Register - R/W

Reset = 0x0000 8000

Figure 23-16: EMAC\_MACCFG Register Diagram

Table 23-40: EMAC\_MACCFG Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                              |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 25      | CST      | CRC Stripping.<br>The EMAC_MACCFG.CST bit, when set, directs the MAC to strip the last 4 bytes (FCS) of all frames of Ether type (type field greater than 0x0600) and drop these bytes before forwarding the frame to the application.                                                                               |
| 23      | WD       | Watch Dog Disable.<br>The EMAC_MACCFG.WD bit when set, disables the watchdog timer on the receiver, and can receive frames of up to 16,384 bytes. When this bit is reset, the MAC allows no more than 2,048 bytes (10,240 if JE is set high) of the frame being received and cuts off any bytes received after that. |

**Table 23-40:** EMAC\_MACCFG Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                             |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 22      | JB       | Jabber Disable.<br>The EMAC_MACCFG.JB bit when set, disables the jabber timer on the transmitter, and can transfer frames of up to 16,384 bytes. When this bit is reset, the MAC cuts off the transmitter if the application sends out more than 2,048 bytes of data (10,240 if JE is set high) during transmission.                                                                                |
| 20      | JE       | Jumbo Frame Enable.<br>The EMAC_MACCFG.JE bit when set, direct the MAC to allow Jumbo frames of 9,018 bytes (9,022 bytes for VLAN tagged frames) without reporting a giant frame error in the receive frame status.                                                                                                                                                                                 |
| 19:17   | IFG      | Inter Frame Gap.<br>The EMAC_MACCFG.IFG bits control the minimum IFG between frames during transmission. Note that in Half-Duplex mode, the minimum IFG can be configured for 64 bit times (IFG = 100) only. Lower values are not considered.                                                                                                                                                       |
|         |          | 0                      96 bit times                                                                                                                                                                                                                                                                                                                                                                 |
|         |          | 1                      88 bit times                                                                                                                                                                                                                                                                                                                                                                 |
|         |          | 2                      80 bit times                                                                                                                                                                                                                                                                                                                                                                 |

|         |          | 7                      40 bit times                                                                                                                                                                                                                                                                                                                                                                 |
| 16      | DCRS     | Disable Carrier Sense.<br>The EMAC_MACCFG.DCRS bit, when set, makes the MAC transmitter ignore the CRS signal during frame transmission in Half-Duplex mode. This request results in no errors generated due to Loss of Carrier or No Carrier during such transmission. When this bit is low, the MAC transmitter generates such errors due to Carrier Sense and will even abort the transmissions. |

**Table 23-40:** EMAC\_MACCFG Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14      | FES      | Speed of Operation.<br>The EMAC_MACCFG.FES bit indicates the Ethernet speed as: 0= 10 Mbps and 1= 100 Mbps.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 13      | DO       | Disable Receive Own.<br>The EMAC_MACCFG.DO bit, when set, disables MAC reception of frames when it is transmitting in Half-Duplex mode. When this bit is reset, the MAC receives all packets that are given by the PHY while transmitting. This bit is not applicable if the MAC is operating in Full-Duplex mode.                                                                                                                                                                                                                                                                                                                                                        |
| 12      | LM       | Loopback Mode.<br>The EMAC_MACCFG.LM bit, when set, direct the MAC to operate in internal loopback mode. (The media independent interface pins are not driven or sampled.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 11      | DM       | Duplex Mode.<br>The EMAC_MACCFG.DM bit, when set, direct the MAC to operate in a Full-Duplex mode where it can transmit and receive simultaneously.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 10      | IPC      | IP Checksum.<br>The EMAC_MACCFG.IPC bit, when set, directs the MAC to calculate the 16-bit one's complement of the one's complement sum of all received Ethernet frame payloads. It also checks whether the IPv4 Header checksum (assumed to be bytes 25-26 or 29-30 (VLAN-tagged) of the received Ethernet frame) is correct for the received frame and gives the status in the receive status word. This bit, when set, enables IPv4 checksum checking for received frame payloads' TCP/UDP/ICMP headers. When this bit is reset, the Checksum Offload Engine function in the receiver is disabled and the corresponding PCE and IP HCE status bits are always cleared. |

**Table 23-40:** EMAC\_MACCFG Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                 |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| 9       | DR       | Disable Retry.<br>The EMAC_MACCFG.DR bit, when set, directs the MAC to attempt only 1 transmission. When a collision occurs on the media independent interface, the MAC will ignore the current frame transmission and report a Frame Abort with excessive collision error in the transmit frame status. When this bit is reset, the MAC will attempt retries based on the settings of BL. This bit is applicable only to Half-Duplex mode.                                                                                                |                 |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Retry enabled   |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Retry disabled  |
| 7       | ACS      | Automatic Pad/CRC Stripping.<br>The EMAC_MACCFG.ACS bit, when set, directs the MAC to strip the Pad/FCS field on incoming frames only if the length's field value is less than or equal to 1,500 bytes. All received frames with length field greater than or equal to 1,501 bytes are passed to the application without stripping the Pad/FCS field. When this bit is reset, the MAC will pass all incoming frames to the Host unmodified.                                                                                                |                 |
| 6:5     | BL       | Back Off Limit.<br>The EMAC_MACCFG.BL bit selects the back-off limit, determining the random integer number (r) of slot time delays (4,096 bit times for 1000 Mbps and 512 bit times for 10/100 Mbps) the MAC waits before rescheduling a transmission attempt during retries after a collision. This bit is applicable only to Half-Duplex mode. The random integer r takes the value in the range:<br>0 less-than-equal-to r less-than 2 <sup>k</sup><br>Where k is the minimum of n (number of transmission attempts) or a limit value. |                 |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | k = min (n, 10) |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | k = min (n, 8)  |

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4       | DC       | <p>Deferral Check.</p> <p>The <code>EMAC_MACCFG.DC</code> bit, when set, enables the deferral check function in the MAC. The MAC will issue a Frame Abort status, along with the excessive deferral error bit set in the transmit frame status when the transmit state machine is deferred for more than 24,288 bit times in 10/100-Mbps mode. If the Jumbo frame mode is enabled in 10/100-Mbps mode, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active CRS (carrier sense) signal. Deferral time is not cumulative. If the transmitter defers for 10,000 bit times, then transmits, collides, backs off, and then has to defer again after completion of back-off, the deferral timer resets to 0 and restarts. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in Half-Duplex mode.</p> |
| 3       | TE       | <p>Transmitter Enable.</p> <p>The <code>EMAC_MACCFG.TE</code> bit, when set, enables the transmit state machine of the MAC for transmission. When this bit is reset, the MAC transmit state machine is disabled after the completion of the transmission of the current frame, and will not transmit any further frames.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 2       | RE       | <p>Receiver Enable.</p> <p>The <code>EMAC_MACCFG.RE</code> bit, when set, enables the receiver state machine of the MAC for receiving frames. When this bit is reset, the MAC receive state machine is disabled after the completion of the reception of the current frame, and will not receive any further frames.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## MAC Rx Frame Filter Register

The `EMAC_MACFRMFILT` register controls receive frame filter features.

**EMAC\_MACFRMFILT: MAC Rx Frame Filter Register - R/W**

Reset = 0x0000 0000

**Figure 23-17:** EMAC\_MACFRMFILT Register Diagram

**Table 23-41:** EMAC\_MACFRMFILT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31      | RA       | Receive All Frames.<br>The EMAC_MACFRMFILT . RA bit, when set, directs the MAC Receiver module to pass to the Application all frames received irrespective of whether they pass the address filter. The result of the DA filtering is updated (pass or fail) in the corresponding bits in the Receive Status Word. When this bit is reset, the Receiver module passes to the Application only those frames that pass the DA address filter. |
| 10      | HPF      | Hash or Perfect Filter.<br>The EMAC_MACFRMFILT . HPF bit. when set, configures the address filter to pass a frame if it matches either the perfect filtering or the hash filtering as set by HMC or HUC bits. When low and if the HUC/HMC bit is set, the frame is passed only if it matches the Hash filter.                                                                                                                               |

| 5       | DBF      | Disable Broadcast Frames.<br>The EMAC_MACFRMFILT . DBF bit, when set, directs the AFM module to filter all incoming broadcast frames. When this bit is reset, the AFM module passes all received broadcast frames                                                          |                                                                                                                                          |
|         |          | 0                                                                                                                                                                                                                                                                          | AFM module passes all received broadcast frames                                                                                          |
|         |          | 1                                                                                                                                                                                                                                                                          | AFM module filters all incoming broadcast frames                                                                                         |
| 4       | PM       | Pass All Multicast Frames.<br>The EMAC_MACFRMFILT . PM bit, when set, indicates that all received frames with a multicast destination address (first bit in the destination address field is '1') are passed. When reset, filtering of multicast frame depends on HMC bit. |                                                                                                                                          |

**Table 23-41:** EMAC\_MACFRMFILT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                        |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3       | DAIF     | Destination Address Inverse Filtering.<br>The EMAC_MACFRMFILT.DAIF bit, when set, directs the Address Check block to operate in inverse filtering mode for the DA address comparison for both unicast and multicast frames. When reset, normal filtering of frames is performed.                                                                               |
| 2       | HMC      | Hash Multicast.<br>The EMAC_MACFRMFILT.HMC bit, when set, directs the EMAC to perform destination address filtering of received multicast frames according to the hash table. When reset, the MAC performs a perfect destination address filtering for multicast frames, that is, it compares the DA field with the values programmed in MAC Address Register. |
| 1       | HUC      | Hash Unicast.<br>The EMAC_MACFRMFILT.HUC bit, when set, directs the EMAC to perform destination address filtering of unicast frames according to the hash table. When reset, the MAC performs a perfect destination address filtering for unicast frames, that is, it compares the DA field with the values programmed in DA registers.                        |
| 0       | PR       | Promiscuous Mode.<br>The EMAC_MACFRMFILT.PR bit, when set, directs the Address Filter module to pass all incoming frames regardless of its destination or source address. The DA Filter Fails status bits of the Receive Status Word will always be cleared when PR is set.                                                                                    |

## Hash Table High Register

The EMAC\_HASHTBL\_HI register contains the upper 32 bits of the hash table.

EMAC\_HASHTBL\_HI: Hash Table High Register - R/W

Reset = 0x0000 0000

## SMI Address Register

The EMAC\_SMI\_ADDR register contains the station management interface address and feature settings.

**EMAC\_SMI\_ADDR: SMI Address Register - R/W**

Reset = 0x0000 0000

**Figure 23-20:** EMAC\_SMI\_ADDR Register Diagram

**Table 23-44:** EMAC\_SMI\_ADDR Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                        |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:11   | PA       | Physical Layer Address.<br>The EMAC_SMI_ADDR.PA bits select the PHY. This field tells which of the 32 possible PHY devices are being accessed. |
| 10:6    | SMIR     | SMI Register Address.<br>The EMAC_SMI_ADDR.SMIR bits select the desired Station Management Interface register in the selected PHY device.      |

**Table 23-44:** EMAC\_SMI\_ADDR Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5:2     | CR       | <p><b>Clock Range.</b><br/>The EMAC_SMI_ADDR.CR bits select the Clock Range, determining the frequency of the MDC clock as per the "SCLK" frequency. The suggested range of SCLK frequency applicable for each value below (when Bit[5] = 0) ensures that the MDC clock is approximately between the frequency range 1.0 MHz - 2.5 MHz. When bit 5 is set, you can achieve MDC clock of frequency higher than the IEEE 802.3 specified frequency limit of 2.5 MHz and program a clock divider of lower value. For example, when SCLK is of frequency 100 MHz and you program these bits as "1010", then the resultant MDC clock will be of 12.5 MHz which is outside the limit of IEEE 802.3 specified range. Please program the values given below only if the interfacing chips supports faster MDC clocks.</p> |
|         |          | 0 MDC Clock=SCLK/42<br>(for SCLK=60-100MHz)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|         |          | 1 MDC Clock= SCLK/62<br>(for SCLK=100-125 MHz)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1       | SMIW     | SMI Write.<br>The EMAC_SMI_ADDR.SMIW bit, when set, tells the PHY that this will be a Write operation using the Station Management Interface Data register. If this bit is not set, this will be a Read operation.                                                                                                                                                                                                                                                                                                                                              |
| 0       | SMIB     | SMI Busy.<br>The EMAC_SMI_ADDR.SMIB bit should read a logic 0 before writing to SMI_ADDR and SMI_DATA. This bit must also be set to 0 during a Write to SMI_ADDR. During a PHY register access, this bit will be set to 1'b1 by the Application to indicate that a Read or Write access is in progress. SMI_DATA should be kept valid until this bit is cleared by the MAC during a PHY Write operation. SMI_DATA is invalid until this bit is cleared by the MAC during a PHY Read operation. The SMI_ADDR should not be written to until this bit is cleared. |

## SMI Data Register

The EMAC\_SMI\_DATA register contains the station management interface data.

### EMAC\_SMI\_DATA: SMI Data Register - R/W

Reset = 0x0000 0000

**Figure 23-21:** EMAC\_SMI\_DATA Register Diagram

**Table 23-45:** EMAC\_SMI\_DATA Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                           |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0    | SMID     | SMI Data.<br>The EMAC_SMI_DATA.SMID bits contain the 16-bit data value read from the PHY after a Management Read operation or the 16-bit data value to be written to the PHY before a Management Write operation. |

## Flow Control Register

The EMAC\_FLOWCTL register controls EMAC flow control features.

**EMAC\_FLOWCTL: Flow Control Register - R/W**

Reset = 0x0000 0000

Figure 23-22: EMAC\_FLOWCTL Register Diagram

Table 23-46: EMAC\_FLOWCTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16   | PT       | Pause Time.<br>The EMAC_FLOWCTL . PT bits hold the value to be used in the Pause Time field in the transmit control frame.                                                                                                                                                                                                                                                                                                               |
| 3       | UP       | Unicast Pause Frame Detect.<br>The EMAC_FLOWCTL . UP bit, when set, directs the MAC to detect the Pause frames with the station's unicast address specified in MAC Address0 High Register and MAC Address0 Low Register, in addition to the detecting Pause frames with the unique multicast address. When this bit is reset, the MAC will detect only a Pause frame with the unique multicast address specified in the 802.3x standard. |
| 2       | RFE      | Receive Flow Control Enable.<br>The EMAC_FLOWCTL . RFE bit, when set, directs the MAC to decode the received Pause frame and disable its transmitter for a specified (Pause Time) time. When this bit is reset, the decode function of the Pause frame is disabled.                                                                                                                                                                      |

**Table 23-46:** EMAC\_FLOWCTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1       | TFE      | Transmit Flow Control Enable.<br>In Full-Duplex mode, when the EMAC_FLOWCTL.TFE bit is set, the MAC enables the flow control operation to transmit Pause frames. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC will not transmit any Pause frames. In Half-Duplex mode, when this bit is set, the MAC enables the back pressure operation. When this bit is reset, the back pressure feature is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 0       | FCBBPA   | Initiate Pause Control Frame.<br>The EMAC_FLOWCTL.FCBBPA bit initiates a Pause Control frame in Full-Duplex mode and activates the backpressure function in Half-Duplex mode if TFE bit is set. In Full-Duplex mode, this bit should be read as 1'b0 before writing to the Flow Control register. To initiate a Pause control frame, the Application must set this bit to 1'b1. During a transfer of the Control Frame, this bit will continue to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC will reset this bit to 1'b0. The Flow Control register should not be written to until this bit is cleared. In Half-Duplex mode, when this bit is set (and TFE is set), then backpressure is asserted by the MAC Core. During backpressure, when the MAC receives a new frame, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically OR'ed with the flow control input signal for the backpressure function. When the MAC is configured to Full-Duplex mode, the BPA is automatically disabled. |

## VLAN Tag Register

The EMAC\_VLANTAG register contains the VLAN tag.

EMAC\_VLANTAG: VLAN Tag Register - R/W

Reset = 0x0000 0000

Figure 23-23: EMAC\_VLANTAG Register Diagram

Table 23-47: EMAC\_VLANTAG Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16      | ETV      | Enable Tag VLAN Comparison.<br>The EMAC_VLANTAG.ETV bit, when set, directs the EMAC to use a 12-bit VLAN identifier, rather than the complete 16-bit VLAN tag, for comparison and filtering. Bits[11:0] of the VLAN tag are compared with the corresponding field in the received VLAN-tagged frame. When this bit is reset, all 16 bits of the received VLAN frame's fifteenth and sixteenth bytes are used for comparison.                                                                                                                                                                                                                             |
| 15:0    | VL       | VLAN Tag Id Receive Frames.<br>The EMAC_VLANTAG.VL bits contain the 802.1Q VLAN tag to identify VLAN frames, and is compared to the fifteenth and sixteenth bytes of the frames being received for VLAN frames. Bits[15:13] are the User Priority, Bit[12] is the Canonical Format Indicator (CFI) and bits[11:0] are the VLAN tag's VLAN Identifier (VID) field. When the ETV bit is set, only the VID (Bits[11:0]) is used for comparison. If VL (VL[11:0] if ETV is set) is all zeros, the MAC does not check the fifteenth and sixteenth bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 to be VLAN frames. |

Debug Register

The EMAC\_DBG register contains EMAC debug status information.

**EMAC\_DBG: Debug Register - R/W**

Reset = 0x0000 0000

**Figure 23-24:** EMAC\_DBG Register Diagram

**Table 23-48:** EMAC\_DBG Register Fields

| Bit No. | Bit Name    | Description/Enumeration                                                                                                                                                                                                                                                              |
|---------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 25      | TXFIFOFULL  | Tx FIFO Full.<br>The EMAC_DBG.TXFIFOFULL bit, when high, indicates that the MFL TxStatus FIFO is full and hence the MFL cannot accept any more frames for transmission.                                                                                                              |
| 24      | TXFIFONE    | Tx FIFO Not Empty.<br>The EMAC_DBG.TXFIFONE bit, when high, indicates that the MFL TxFIFO is not empty and has some data left for transmission.                                                                                                                                      |
| 22      | TXFIFOACT   | Tx FIFO Active.<br>The EMAC_DBG.TXFIFOACT bit, when high, indicates that the MFL TxFIFO write controller is active and transferring data to the TxFIFO.                                                                                                                              |
| 21:20   | TXFIFOCTLST | Tx FIFO Controller State.<br>The EMAC_DBG.TXFIFOCTLST bits indicate the state of the TxFIFO read controller: 00 IDLE state 01 READ state (transferring data to MAC transmitter) 10 Waiting for TxStatus from MAC transmitter 11 Writing the received TxStatus or flushing the TxFIFO |

**Table 23-48:** EMAC\_DBG Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                   |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19      | TXPAUSE  | Tx Paused.<br>The EMAC_DBG.TXPAUSE bit, when high, indicates that the MAC transmitter is in PAUSE condition (in full-duplex only) and hence does not schedule any frame for transmission. |
| 18:17   | TXFRCTL  | Tx Frame Controller State.<br>The EMAC_DBG.TXFRCTL bits indicate the state of the MAC transmit frame controller module.                                                                   |

**Table 23-48:** EMAC\_DBG Register Fields (Continued)

| Bit No. | Bit Name    | Description/Enumeration                                                                                                                                                                    |
|---------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6:5     | RXFIFOCTLST | Rx FIFO Controller State.<br>The EMAC_DBG.RXFIFOCTLST bits give the state of the RxFIFO read controller.                                                                                   |
|         |             | 0<br>Idle<br>Read controller is in idle state.                                                                                                                                             |
|         |             | 1<br>Read Data<br>Read controller is reading frame data.                                                                                                                                   |
|         |             | 2<br>Read Status<br>Read controller is reading frame status or time-stamp.                                                                                                                 |
|         |             | 3<br>Flush<br>Read controller is flushing the frame data and status.                                                                                                                       |
| 4       | RXFIFOACT   | Rx FIFO Active.<br>The EMAC_DBG.RXFIFOACT bit, when high, indicates that the MFL RxFIFO write controller is active and transferring a received frame to the FIFO.                          |
| 2:1     | SFIFOST     | Small FIFO State.<br>The EMAC_DBG.SFIFOST bit, when high, indicates the active state of the small FIFO read and write controllers respectively of the MAC receive frame controller module. |
| 0       | MMREA       | MM Rx Engine Active.<br>The EMAC_DBG.MMREA bit, when high, indicates that the MAC core receive protocol engine is actively receiving data and not in IDLE state.                           |

## Interrupt Status Register

The EMAC\_ISTAT register indicates EMAC interrupt status.

**EMAC\_ISTAT: Interrupt Status Register - R/W**

Reset = 0x0000 0000

**Figure 23-25:** EMAC\_ISTAT Register Diagram

**Table 23-49:** EMAC\_ISTAT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9       | TS       | <p>Time Stamp Interrupt Status.</p> <p>When Advanced Time Stamping feature is enabled, the EMAC_ISTAT.TS bit is set when:</p> <ul style="list-style-type: none"> <li>The system time value equals or exceeds the value specified in the Target Time High and Low registers, or</li> <li>There is an overflow in the seconds register, or</li> <li>When the Auxiliary snapshot trigger is asserted.</li> </ul> <p>This bit is cleared on reading the byte 0 of the "Time Stamp Status register". Otherwise, when default Time-Stamping is enabled, this bit when set indicates that the system time value equals or exceeds the value specified in the Target Time registers. In this mode, this bit is cleared after the completion of the read of this Interrupt Status Register. In all other modes, this bit is reserved.</p> |
| 7       | MMCRC    | <p>MMC Receive Checksum Offload Interrupt Status.</p> <p>The EMAC_ISTAT.MMCRC bit is set high whenever an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all the bits in this interrupt register are cleared.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 6       | MMCTX    | <p>MMC Transmit Interrupt Status.</p> <p>The EMAC_ISTAT.MMCTX bit is set high whenever an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all the bits in this interrupt register are cleared.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Table 23-49:** EMAC\_ISTAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                       |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5       | MMCRX    | MMC Receive Interrupt Status.<br>The EMAC_ISTAT.MMCRX bit is set high whenever an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all the bits in this interrupt register are cleared. |
| 4       | MMC      | MMC Interrupt Status.<br>The EMAC_ISTAT.MMC bit is set high whenever any of bits 7:5 is set high and cleared only when all of these bits are low.                                                                             |

## Interrupt Mask Register

The EMAC\_IMSK register enables (unmasks) EMAC interrupts.

**EMAC\_IMSK: Interrupt Mask Register - R/W**

Reset = 0x0000 0000

**Figure 23-26:** EMAC\_IMSK Register Diagram

**Table 23-50:** EMAC\_IMSK Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                               |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9       | TS       | Time Stamp Interrupt Mask.<br>The EMAC_IMSK.TS bit, when set, disables the assertion of the interrupt signal due to the setting of Time Stamp Interrupt Status bit in ISTAT Register. |

## MAC Address 0 High Register

The EMAC\_ADDRO\_HI register holds the address 0 high bits.

EMAC\_ADDR0\_HI: MAC Address 0 High Register - R/W

Reset = 0x8000 ffff

Figure 23-27: EMAC\_ADDR0\_HI Register Diagram

Table 23-51: EMAC\_ADDR0\_HI Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                              |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0    | ADDR     | Address.<br>The EMAC_ADDR0_HI . ADDR bits contain the upper 16 bits (47:32) of the 6-byte first MAC address. This is used by the MAC for filtering for received frames and for inserting the MAC address in the Transmit Flow Control (PAUSE) Frames |

MAC Address 0 Low Register

The EMAC\_ADDR0\_LO register holds the address 0 low bits.

EMAC\_ADDR0\_LO: MAC Address 0 Low Register - R/W

Reset = 0xffff ffff

Figure 23-28: EMAC\_ADDR0\_LO Register Diagram

Table 23-52: EMAC\_ADDR0\_LO Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                     |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | ADDR     | Address.<br>The EMAC_ADDR0_LO.ADDR bits contain the lower 32 bits of the 6-byte first MAC address. This is used by the MAC for filtering for received frames and for inserting the MAC address in the Transmit Flow Control (PAUSE) Frames. |

MMC Control Register

The EMAC\_MMC\_CTL register selects the MMC operating mode.

EMAC\_MMC\_CTL: MMC Control Register - R/W

Reset = 0x0000 0000

Figure 23-29: EMAC\_MMC\_CTL Register Diagram

**Table 23-53:** EMAC\_MMC\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5       | FULLPSET | <p>Full Preset.</p> <p>The EMAC_MMC_CTL.FULLPSET bit, when low and bit 4 is set, presets all MMC counters to almost-half value. All octet counters get preset to 0x7FFF_F800 (half - 2KBytes) and all frame-counters gets preset to 0x7FFF_FFF0 (half - 16). When high and bit4 is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (full - 2KBytes) and all frame-counters gets preset to 0xFFFF_FFF0 (full - 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and frame counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0.</p> |
| 4       | CNTRPSET | <p>Counter Reset/Preset.</p> <p>The EMAC_MMC_CTL.CNTRPSET bit, when set, initializes all counters or presets counters to almost full or almost half as per Bit 5. This bit is cleared automatically after 1 clock cycle. This bit along with bit5 is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full.</p>                                                                                                                                                                                                                                                                                                                 |
| 3       | CNTRFRZ  | <p>Counter Freeze.</p> <p>The EMAC_MMC_CTL.CNTRFRZ bit, when set, freezes all the MMC counters to their current value. (None of the MMC counters are updated because of any transmitted or received frame until this bit is reset to 0. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.)</p>                                                                                                                                                                                                                                                                                                                                  |
| 2       | RDRST    | <p>Read Reset.</p> <p>The EMAC_MMC_CTL.RDRST bit, when set, resets the MMC counters to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 1       | NOROLL   | <p>No Rollover.</p> <p>The EMAC_MMC_CTL.NOROLL bit, when set, prevents counter rolls over to 0 after reaching max.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 0       | RST      | <p>Reset.</p> <p>The EMAC_MMC_CTL.RST bit, when set, resets all counters. This bit is cleared automatically after 1 clock cycle</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## MMC Rx Interrupt Register

The EMAC\_MMC\_RXINT register indicates status of MMC receive interrupts.

### EMAC\_MMC\_RXINT: MMC Rx Interrupt Register - R/W

Reset = 0x0000 0000

Figure 23-30: EMAC\_MMC\_RXINT Register Diagram

**Table 23-54:** EMAC\_MMC\_RXINT Register Fields

| Bit No. | Bit Name   | Description/Enumeration                                                                                                                               |
|---------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 23      | WDOGERR    | Rx Watch Dog Error Count Half/Full.<br>The EMAC_MMC_RXINT.WDOGERR bit is set when rxwatchdog_error counter reaches full or half.                      |
| 22      | VLANFRGB   | Rx VLAN Frames (Good/Bad) Count Half/Full.<br>The EMAC_MMC_RXINT.VLANFRGB bit is set when rxvlanframes_gb counter reaches full or half.               |
| 21      | FIFOOVF    | Rx FIFO Overflow Count Half/Full.<br>The EMAC_MMC_RXINT.FIFOOVF bit is set when rxffiooverflow counter reaches full or half.                          |
| 20      | PAUSEFR    | Rx Pause Frames Count Half/Full.<br>The EMAC_MMC_RXINT.PAUSEFR bit is set when rxpauseframes counter reaches full or half.                            |
| 19      | OUTRANGE   | Rx Out Of Range Type Count Half/Full.<br>The EMAC_MMC_RXINT.OUTRANGE bit is set when rxoutofrangetype counter reaches full or half.                   |
| 18      | LENERR     | Rx Length Error Count Half/Full.<br>The EMAC_MMC_RXINT.LENERR bit is set when rxlengtherror counter reaches full or half.                             |
| 17      | UCASTG     | Rx Unicast Frames (Good) Count Half/Full.<br>The EMAC_MMC_RXINT.UCASTG bit is set when rxunicastframes_g counter reaches full or half.                |
| 16      | R1024TOMAX | Rx 1024-to-max Octets (Good/Bad) Count Half/Full.<br>The EMAC_MMC_RXINT.R1024TOMAX bit is set when rx1024tomaxoctets_gb counter reaches full or half. |
| 15      | R512TO1023 | Rx 512-to-1023 Octets (Good/Bad) Count Half/Full.<br>The EMAC_MMC_RXINT.R512TO1023 bit is set when rx512to1023octets_gb counter reaches full or half. |
| 14      | R256TO511  | Rx 255-to-511 Octets (Good/Bad) Count Half/Full.<br>The EMAC_MMC_RXINT.R256TO511 bit is set when rx255to511octets_gb counter reaches full or half.    |

**Table 23-54:** EMAC\_MMC\_RXINT Register Fields (Continued)

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                            |
|---------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 13      | R128TO255 | Rx 128-to-255 Octets (Good/Bad) Count Half/Full.<br>The EMAC_MMC_RXINT.R128TO255 bit is set when rx128to255octets_gb counter reaches full or half. |
| 12      | R65TO127  | Rx 65-to-127 Octets (Good/Bad) Count Half/Full.<br>The EMAC_MMC_RXINT.R65TO127 bit is set when rx65to127octets_gb counter reaches full or half.    |
| 11      | R64       | Rx 64 Octets (Good/Bad) Count Half/Full.<br>The EMAC_MMC_RXINT.R64 bit is set when rx64octets_gb counter reaches full or half.                     |
| 10      | OSIZEG    | Rx Oversize (Good) Count Half/Full.<br>The EMAC_MMC_RXINT.OSIZEG bit is set when rxoversize_g counter reaches full or half.                        |
| 9       | USIZEG    | Rx Undersize (Good) Count Half/Full.<br>The EMAC_MMC_RXINT.USIZEG bit is set when rxundersize_g counter reaches full or half.                      |
| 8       | JABERR    | Rx Jabber Error Count Half/Full.<br>The EMAC_MMC_RXINT.JABERR bit is set when rxjabbererror counter reaches full or half.                          |
| 7       | RUNTERR   | Rx Runt Error Count Half/Full.<br>The EMAC_MMC_RXINT.RUNTERR bit is set when rxrunterror counter reaches full or half.                             |
| 6       | ALIGNERR  | Rx Alignment Error Count Half/Full.<br>The EMAC_MMC_RXINT.ALIGNERR bit is set when rxalignmenterror counter reaches full or half                   |
| 5       | CRCERR    | Rx CRC Error Counter Half/Full.<br>The EMAC_MMC_RXINT.CRCERR bit is set when rxcrcerror counter reaches full or half.                              |
| 4       | MCASTG    | Rx Multicast Count (Good) Half/Full.<br>The EMAC_MMC_RXINT.MCASTG bit is set when rxmulticastframes_g counter reaches full or half.                |
| 3       | BCASTG    | Rx Broadcast Count (Good) Half/Full.<br>The EMAC_MMC_RXINT.BCASTG bit is set when rxbroadcastframes_g counter reaches full or half.                |

**Table 23-54:** EMAC\_MMC\_RXINT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                        |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------|
| 2       | OCTCNTG  | Octet Count (Good) Half/Full.<br>The EMAC_MMC_RXINT.OCTCNTG bit is set when rxoctetcount_g counter reaches full or half.       |
| 1       | OCTCNTGB | Octet Count (Good/Bad) Half/Full.<br>The EMAC_MMC_RXINT.OCTCNTGB bit is set when rxoctetcount_gb counter reaches half or full. |
| 0       | FRCNTGB  | Frame Count (Good/Bad) Half/Full.<br>The EMAC_MMC_RXINT.FRCNTGB bit is set when rxframecount_gb counter reaches half or full.  |

## MMC Tx Interrupt Register

The EMAC\_MMC\_TXINT register indicates status of MMC transmit interrupts.

# EMAC\_MMC\_TXINT: MMC Tx Interrupt Register - R/W

Reset = 0x0000 0000

Figure 23-31: EMAC\_MMC\_TXINT Register Diagram

**Table 23-55:** EMAC\_MMC\_TXINT Register Fields

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                 |
|---------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------|
| 24      | VLANFRGB  | Tx VLAN Frames (Good) Count Half/Full.<br>The EMAC_MMC_TXINT.VLANFRGB bit is set when txvlanframes_g counter reaches full or half.      |
| 23      | PAUSEFRM  | Tx Pause Frames Count Half/Full.<br>The EMAC_MMC_TXINT.PAUSEFRM bit is set when txpauseframes counter reaches full or half.             |
| 22      | EXCESSDEF | Tx Excess Deferred Count Half/Full.<br>The EMAC_MMC_TXINT.EXCESSDEF bit is set when txexcessdef counter reaches full or half.           |
| 21      | FRCNTG    | Tx Frame Count (Good) Count Half/Full.<br>The EMAC_MMC_TXINT.FRCNTG bit is set when txframecount_g counter reaches full or half.        |
| 20      | OCTCNTG   | Tx Octet Count (Good) Count Half/Full.<br>The EMAC_MMC_TXINT.OCTCNTG bit is set when txoctetcount_g counter reaches full or half.       |
| 19      | CARRERR   | Tx Carrier Error Count Half/Full.<br>The EMAC_MMC_TXINT.CARRERR bit is set when txcarriererr counter reaches full or half.              |
| 18      | EXCESSCOL | Tx Excess Collision Count Half/Full.<br>The EMAC_MMC_TXINT.EXCESSCOL bit is set when txexesscol counter reaches full or half.           |
| 17      | LATECOL   | Tx Late Collision Count Half/Full.<br>The EMAC_MMC_TXINT.LATECOL bit is set when txlatecol counter reaches full or half.                |
| 16      | DEFERRED  | Tx Deffered Count Half/Full.<br>The EMAC_MMC_TXINT.DEFERRED bit is set when txdeffered counter reaches full or half.                    |
| 15      | MULTCOLG  | Tx Multiple collision (Good) Count Half/Full.<br>The EMAC_MMC_TXINT.MULTCOLG bit is set when txmulticol_g counter reaches full or half. |

**Table 23-55:** EMAC\_MMC\_TXINT Register Fields (Continued)

| Bit No. | Bit Name   | Description/Enumeration                                                                                                                               |
|---------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14      | SNGCOLG    | Tx Single Collision (Good) Count Half/Full.<br>The EMAC_MMC_TXINT.SNGCOLG bit is set when txsinglecol_g counter reaches full or half.                 |
| 13      | UNDERR     | Tx Underflow Error Count Half/Full.<br>The EMAC_MMC_TXINT.UNDERR bit is set when txunderflowerror counter reaches full or half.                       |
| 12      | BCASTGB    | Tx Broadcast Frames (Good/Bad) Count Half/Full.<br>The EMAC_MMC_TXINT.BCASTGB bit is set when txbroadcastframes_gb counter reaches full or half.      |
| 11      | MCASTGB    | Tx Multicast Frames (Good/Bad) Count Half/Full.<br>The EMAC_MMC_TXINT.MCASTGB bit is set when txmulticastframes_gb counter reaches full or half.      |
| 10      | UCASTGB    | Tx Unicast Frames (Good/Bad) Count Half/Full.<br>The EMAC_MMC_TXINT.UCASTGB bit is set when txunicastframes_gb counter reaches full or half.          |
| 9       | T1024TOMAX | Tx 1024-to-max Octets (Good/Bad) Count Half/Full.<br>The EMAC_MMC_TXINT.T1024TOMAX bit is set when tx1024tomaxoctets_gb counter reaches full or half. |
| 8       | T512TO1023 | Tx 512-to-1023 Octets (Good/Bad) Count Half/Full.<br>The EMAC_MMC_TXINT.T512TO1023 bit is set when tx512to1023octets_gb counter reaches full or half. |
| 7       | T256TO511  | Tx 256-to-511 Octets (Good/Bad) Count Half/Full.<br>The EMAC_MMC_TXINT.T256TO511 bit is set when tx256to511octets_gb counter reaches full or half.    |

| 5       | T65TO127   | Tx 65-to-127 Octets (Good/Bad) Count Half/Full.<br>The EMAC_MMC_TXINT.T65TO127 bit is set when tx65to127octets_gb counter reaches full or half.       |
| 4       | T64        | Tx 64 Octets (Good/Bad) Count Half/Full.<br>The EMAC_MMC_TXINT.T64 bit is set when tx64octets_gb counter reaches full or half.                        |

**Table 23-55:** EMAC\_MMC\_TXINT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                    |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------|
| 3       | MCASTG   | Tx Multicast Frames (Good) Count Half/Full.<br>The EMAC_MMC_TXINT.MCASTG bit is set when txmulticastframes_g counter reaches full or half. |
| 2       | BCASTG   | Tx Broadcast Frames (Good) Count Half/Full.<br>The EMAC_MMC_TXINT.BCASTG bit is set when txbroadcastframes_g counter reaches full or half. |
| 1       | FRCNTGB  | Tx Frame Count (Good/Bad) Count Half/Full.<br>The EMAC_MMC_TXINT.FRCNTGB bit is set when txframecount_gb counter reaches full or half.     |
| 0       | OCTCNTGB | Tx Octet Count (Good/Bad) Count Half/Full.<br>The EMAC_MMC_TXINT.OCTCNTGB bit is set when txoctetcount_gb counter reaches full or half.    |

## MMC Rx Interrupt Mask Register

The EMAC\_MMC\_RXIMSK register enables (unmasks) MMC receive interrupts.

# EMAC\_MMC\_RXIMSK: MMC Rx Interrupt Mask Register - R/W

Reset = 0x0000 0000

Figure 23-32: EMAC\_MMC\_RXIMSK Register Diagram

Table 23-56: EMAC\_MMC\_RXIMSK Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                         |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 23      | WATCHERR | Rx Watch Dog Error Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.WATCHERR bit, when set, masks the interrupt when rxwatchdog_error counter reaches full or half. |

**Table 23-56:** EMAC\_MMC\_RXIMSK Register Fields (Continued)

| Bit No. | Bit Name   | Description/Enumeration                                                                                                                                                             |
|---------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 22      | VLANFRGB   | Rx VLAN Frames (Good/Bad) Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.VLANFRGB bit, when set, masks the interrupt when rxvlanframes_gb counter reaches full or half.               |
| 21      | FIFOOV     | Rx FIFO Overflow Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.FIFOOV bit, when set, masks the interrupt when rxffiooverflow counter reaches full or half.                           |
| 20      | PAUSEFRM   | Rx Pause Frames Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.PAUSEFRM bit, when set, masks the interrupt when rxpauseframes counter reaches full or half.                           |
| 19      | OUTRANGE   | Rx Out Of Range Type Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.OUTRANGE bit, when set, masks the interrupt when rxoutofrangetype counter reaches full or half.                   |
| 18      | LENERR     | Rx Length Error Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.LENERR bit, when set, masks the interrupt when rxlengtherror counter reaches full or half.                             |
| 17      | UCASTG     | Rx Unicast Frames (Good) Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.UCASTG bit, when set, masks the interrupt when rxunicastframes_g counter reaches full or half.                |
| 16      | R1024TOMAX | Rx 1024-to-max Octets (Good/Bad) Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.R1024TOMAX bit, when set, masks the interrupt when rx1024tomaxoctets_gb counter reaches full or half. |
| 15      | R512TO1023 | Rx 512-to-1023 Octets (Good/Bad) Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.R512TO1023 bit, when set, masks the interrupt when rx512to1023octets_gb counter reaches full or half. |
| 14      | R256TO511  | Rx 255-to-511 Octets (Good/Bad) Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.R256TO511 bit, when set, masks the interrupt when rx255to511octets_gb counter reaches full or half.    |
| 13      | R128TO255  | Rx 128-to-255 Octets (Good/Bad) Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.R128TO255 bit, when set, masks the interrupt when rx128to255octets_gb counter reaches full or half.    |
| 12      | R65TO127   | Rx 65-to-127 Octets (Good/Bad) Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.R65TO127 bit, when set, masks the interrupt when rx65to127octets_gb counter reaches full or half.       |

**Table 23-56:** EMAC\_MMC\_RXIMSK Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                  |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11      | R64      | Rx 64 Octets (Good/Bad) Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.R64 bit, when set, masks the interrupt when rx64octets_gb counter reaches full or half.             |
| 10      | OSIZEG   | Rx Oversize (Good) Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.OSIZEG bit, when set, masks the interrupt when rxoversize_g counter reaches full or half.                |
| 9       | USIZEG   | Rx Undersize (Good) Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.USIZEG bit, when set, masks the interrupt when rxundersize_g counter reaches full or half.              |
| 8       | JABERR   | Rx Jabber Error Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.JABERR bit, when set, masks the interrupt when rxjabbererror counter reaches full or half.                  |
| 7       | RUNTERR  | Rx Runt Error Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.RUNTERR bit, when set, masks the interrupt when rxrunterror counter reaches full or half.                     |
| 6       | ALIGNERR | Rx Alignment Error Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.ALIGNERR bit, when set, masks the interrupt when rxalignmenterror counter reaches full or half.          |
| 5       | CRCERR   | Rx CRC Error Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.CRCERR bit, when set, masks the interrupt when rxrcerror counter reaches full or half.                         |
| 4       | MCASTG   | Rx Multicast Frames (Good) Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.MCASTG bit, when set, masks the interrupt when rxmulticastframes_g counter reaches full or half. |
| 3       | BCASTG   | Rx Broadcast Frames (Good) Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.BCASTG bit, when set, masks the interrupt when rxbroadcastframes_g counter reaches full or half. |
| 2       | OCTCNTG  | Rx Octet Count (Good) Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.OCTCNTG bit, when set, masks the interrupt when rxoctetcount_g counter reaches full or half.          |
| 1       | OCTCNTGB | Rx Octet Count (Good/Bad) Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.OCTCNTGB bit, when set, masks the interrupt when rxoctetcount_gb counter reaches half or full.    |

**Table 23-56:** EMAC\_MMC\_RXIMSK Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                              |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0       | FRCNTGB  | Rx Frame Count (Good/Bad) Count Half/Full Mask.<br>The EMAC_MMC_RXIMSK.FRCNTGB bit, when set, masks the interrupt when rxframecount_gb counter reaches half or full. |

## MMC TX Interrupt Mask Register

The EMAC\_MMC\_TXIMSK register enables (unmasks) MMC transmit interrupts.

# EMAC\_MMC\_TXIMSK: MMC TX Interrupt Mask Register - R/W

Reset = 0x0000 0000

Figure 23-33: EMAC\_MMC\_TXIMSK Register Diagram

**Table 23-57:** EMAC\_MMC\_TXIMSK Register Fields

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                         |
|---------|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 24      | VLANFRG   | Tx VLAN Frames (Good) Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.VLANFRG bit, when set, masks the interrupt when txvlanframes_g counter reaches full or half. |
| 23      | PAUSEFRM  | Tx Pause Frames Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.PAUSEFRM bit, when set, masks the interrupt when txpauseframes counter reaches full or half.       |
| 22      | EXCESSDEF | Tx Excess Deferred Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.EXCESSDEF bit, when set, masks the interrupt when txexcessdef counter reaches full or half.     |
| 21      | FRCNTG    | Tx Frame Count (Good) Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.FRCNTG bit, when set, masks the interrupt when txframecount_g counter reaches full or half.  |
| 20      | OCTCNTG   | Tx Octet Count (Good) Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.OCTCNTG bit, when set, masks the interrupt when txoctetcount_g counter reaches full or half. |
| 19      | CARRERR   | Tx Carrier Error Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.CARRERR bit, when set, masks the interrupt when txcarriererr counter reaches full or half.        |
| 18      | EXCESSCOL | Tx Excess collision Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.EXCESSCOL bit, when set, masks the interrupt when txexesscol counter reaches full or half.     |
| 17      | LATECOL   | Tx Late Collision Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.LATECOL bit, when set, masks the interrupt when txlatecol counter reaches full or half.          |
| 16      | DEFERRED  | Tx Deferred Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.DEFERRED bit, when set, masks the interrupt when txdeferred counter reaches full or half.              |
| 15      | MULTCOLG  | Tx Multiple Collisions (Good) Count Mask.<br>The EMAC_MMC_TXIMSK.MULTCOLG bit, when set, masks the interrupt when txmulticol_g counter reaches full or half.    |

**Table 23-57:** EMAC\_MMC\_TXIMSK Register Fields (Continued)

| Bit No. | Bit Name   | Description/Enumeration                                                                                                                                                             |
|---------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14      | SNGCOLG    | Tx Single Collision (Good) Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.SNGCOLG bit, when set, masks the interrupt when txsinglecol_g counter reaches full or half.                 |
| 13      | UNDERR     | Tx Underflow Error Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.UNDERR bit, when set, masks the interrupt when txunderflowerror counter reaches full or half.                       |
| 12      | BCASTGB    | Tx Broadcast Frames (Good/Bad) Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.BCASTGB bit, when set, masks the interrupt when txbroadcastframes_gb counter reaches full or half.      |
| 11      | MCASTGB    | Tx Multicast Frames (Good/Bad) Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.MCASTGB bit, when set, masks the interrupt when txmulticastframes_gb counter reaches full or half.      |
| 10      | UCASTGB    | Tx Unicast Frames (Good/Bad) Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.UCASTGB bit, when set, masks the interrupt when txunicastframes_gb counter reaches full or half.          |
| 9       | T1024TOMAX | Tx 1024-to-max Octets (Good/Bad) Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.T1024TOMAX bit, when set, masks the interrupt when tx1024tomaxoctets_gb counter reaches full or half. |

| 4       | T64        | Tx 64 Octets (Good/Bad) Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.T64 bit, when set, masks the interrupt when tx64octets_gb counter reaches full or half.                        |

Table 23-57: EMAC\_MMC\_TXIMSK Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                  |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3       | MCASTG   | Tx Multicast Frames (Good) Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.MCASTG bit, when set, masks the interrupt when txmulticastframes_g counter reaches full or half. |
| 2       | BCASTG   | Tx Broadcast Frames (Good) Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.BCASTG bit, when set, masks the interrupt when txbroadcastframes_g counter reaches full or half. |
| 1       | FRCNTGB  | Tx Frame Count (Good/Bad) Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.FRCNTGB bit, when set, masks the interrupt when txframecount_gb counter reaches full or half.     |
| 0       | OCTCNTGB | Tx Octet Count (Good/Bad) Count Half/Full Mask.<br>The EMAC_MMC_TXIMSK.OCTCNTGB bit, when set, masks the interrupt when txoctetcount_gb counter reaches full or half.    |

Tx OCT Count (Good/Bad) Register

The EMAC\_TXOCTCNT\_GB register contains the count of the number of bytes transmitted, exclusive of the preamble and retried bytes, in good and bad frames.

EMAC\_TXOCTCNT\_GB: Tx OCT Count (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-34: EMAC\_TXOCTCNT\_GB Register Diagram

Table 23-58: EMAC\_TXOCTCNT\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Tx Frame Count (Good/Bad) Register

The EMAC\_TXFRMCNT\_GB register contains the count of the number of good and bad frames transmitted, exclusive of retried frames.

EMAC\_TXFRMCNT\_GB: Tx Frame Count (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-35: EMAC\_TXFRMCNT\_GB Register Diagram

Table 23-59: EMAC\_TXFRMCNT\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Tx Broadcast Frames (Good) Register

The EMAC\_TXBCASTFRM\_G register contains the count of the number of good broadcast frames transmitted.

EMAC\_TXBCASTFRM\_G: Tx Broadcast Frames (Good) Register - R/NW

Reset = 0x0000 0000

Figure 23-36: EMAC\_TXBCASTFRM\_G Register Diagram

Table 23-60: EMAC\_TXBCASTFRM\_G Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Tx Multicast Frames (Good) Register

The EMAC\_TXMCASTFRM\_G register contains the count of the number of good multicast frames transmitted.

EMAC\_TXMCASTFRM\_G: Tx Multicast Frames (Good) Register - R/NW

Reset = 0x0000 0000

Figure 23-37: EMAC\_TXMCASTFRM\_G Register Diagram

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Tx 64-Byte Frames (Good/Bad) Register

The EMAC\_TX64\_GB register contains the count of the number of good and bad frames transmitted with length 64 bytes, exclusive of preamble and retried frames.

EMAC\_TX64\_GB: Tx 64-Byte Frames (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-38: EMAC\_TX64\_GB Register Diagram

Table 23-62: EMAC\_TX64\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Tx 65- to 127-Byte Frames (Good/Bad) Register

The EMAC\_TX65TO127\_GB register contains the count of the number of good and bad frames transmitted with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames.

EMAC\_TX65TO127\_GB: Tx 65- to 127-Byte Frames (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-39: EMAC\_TX65TO127\_GB Register Diagram

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Tx 256- to 511-Byte Frames (Good/Bad) Register

The EMAC\_TX256TO511\_GB register contains the count of the number of good and bad frames transmitted with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames.

EMAC\_TX256TO511\_GB: Tx 256- to 511-Byte Frames (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-41: EMAC\_TX256TO511\_GB Register Diagram

**Table 23-65:** EMAC\_TX256TO511\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Tx 512- to 1023-Byte Frames (Good/Bad) Register

The EMAC\_TX512TO1023\_GB register contains the count of the number of good and bad frames transmitted with length between 512 and 1023 (inclusive) bytes, exclusive of preamble and retried frames.

**EMAC\_TX512TO1023\_GB: Tx 512- to 1023-Byte Frames (Good/Bad) Register - R/NW**

Reset = 0x0000 0000

**Figure 23-42:** EMAC\_TX512TO1023\_GB Register Diagram

**Table 23-66:** EMAC\_TX512TO1023\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Tx 1024- to Max-Byte Frames (Good/Bad) Register

The EMAC\_TX1024TOMAX\_GB register contains the count of the number of good and bad frames transmitted with length between 1024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.

EMAC\_TX1024TOMAX\_GB: Tx 1024- to Max-Byte Frames (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-43: EMAC\_TX1024TOMAX\_GB Register Diagram

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Tx Unicast Frames (Good/Bad) Register

The EMAC\_TXUCASTFRM\_GB register contains the count of the number of good and bad unicast frames transmitted.

EMAC\_TXUCASTFRM\_GB: Tx Unicast Frames (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-44: EMAC\_TXUCASTFRM\_GB Register Diagram

Table 23-68: EMAC\_TXUCASTFRM\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Tx Multicast Frames (Good/Bad) Register

The EMAC\_TXMCASTFRM\_GB register contains the count of the number of good and bad multicast frames transmitted.

EMAC\_TXMCASTFRM\_GB: Tx Multicast Frames (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-45: EMAC\_TXMCASTFRM\_GB Register Diagram

Table 23-69: EMAC\_TXMCASTFRM\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Tx Broadcast Frames (Good/Bad) Register

The EMAC\_TXBCASTFRM\_GB register contains the count of the number of good and bad broadcast frames transmitted.

EMAC\_TXBCASTFRM\_GB: Tx Broadcast Frames (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-46: EMAC\_TXBCASTFRM\_GB Register Diagram

Table 23-70: EMAC\_TXBCASTFRM\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Tx Underflow Error Register

The EMAC\_TXUNDR\_ERR register contains a count of the number of frames aborted due to frame underflow error.

EMAC\_TXUNDR\_ERR: Tx Underflow Error Register - R/NW

Reset = 0x0000 0000

Figure 23-47: EMAC\_TXUNDR\_ERR Register Diagram

Table 23-71: EMAC\_TXUNDR\_ERR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Tx Single Collision (Good) Register

The EMAC\_TXSNGCOL\_G register contains a count of the number of successfully transmitted frames after a single collision in Half-duplex mode.

EMAC\_TXSNGCOL\_G: Tx Single Collision (Good) Register - R/NW

Reset = 0x0000 0000

Figure 23-48: EMAC\_TXSNGCOL\_G Register Diagram

Table 23-72: EMAC\_TXSNGCOL\_G Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Tx Multiple Collision (Good) Register

The EMAC\_TXMULTCOL\_G register contains a count of the number of successfully transmitted frames after more than a single collision in Half-duplex mode.

EMAC\_TXMULTCOL\_G: Tx Multiple Collision (Good) Register - R/NW

Reset = 0x0000 0000

Figure 23-49: EMAC\_TXMULTCOL\_G Register Diagram

Table 23-73: EMAC\_TXMULTCOL\_G Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Tx Deferred Register

The EMAC\_TXDEFERRED register contains a count of the number of successfully transmitted frames after a deferral in Half-duplex mode.

**EMAC\_TXDEFERRED: Tx Deferred Register - R/NW**

Reset = 0x0000 0000

Figure 23-50: EMAC\_TXDEFERRED Register Diagram

Table 23-74: EMAC\_TXDEFERRED Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Tx Late Collision Register

The EMAC\_TXLATECOL register contains a count of the number of frames aborted due to late collision error.

**EMAC\_TXLATECOL: Tx Late Collision Register - R/NW**

Reset = 0x0000 0000

Figure 23-51: EMAC\_TXLATECOL Register Diagram

**Table 23-75:** EMAC\_TXLATECOL Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

**Tx Excess Collision Register**

The EMAC\_TXEXCESSCOL register contains a count of the number of frames aborted due to excessive (16) collision errors.

**EMAC\_TXEXCESSCOL: Tx Excess Collision Register - R/NW**

Reset = 0x0000 0000

**Figure 23-52:** EMAC\_TXEXCESSCOL Register Diagram

**Table 23-76:** EMAC\_TXEXCESSCOL Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

**Tx Carrier Error Register**

The EMAC\_TXCARR\_ERR register contains a count of the number of frames aborted due to carrier sense error (no carrier or loss of carrier).

EMAC\_TXCARR\_ERR: Tx Carrier Error Register - R/NW

Reset = 0x0000 0000

Figure 23-53: EMAC\_TXCARR\_ERR Register Diagram

Table 23-77: EMAC\_TXCARR\_ERR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Tx Octet Count (Good) Register

The EMAC\_TXOCTCNT\_G register contains a count of the number of bytes transmitted, exclusive of preamble, in good frames only.

EMAC\_TXOCTCNT\_G: Tx Octet Count (Good) Register - R/NW

Reset = 0x0000 0000

Figure 23-54: EMAC\_TXOCTCNT\_G Register Diagram

Table 23-78: EMAC\_TXOCTCNT\_G Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Tx Frame Count (Good) Register

The EMAC\_TXFRMCNT\_G register contains a count of the number of good frames transmitted.

EMAC\_TXFRMCNT\_G: Tx Frame Count (Good) Register - R/NW

Reset = 0x0000 0000

Figure 23-55: EMAC\_TXFRMCNT\_G Register Diagram

Table 23-79: EMAC\_TXFRMCNT\_G Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Tx Excess Deferral Register

The EMAC\_TXEXCESSDEF register contains a count of the number of frames aborted due to excessive deferral error (deferred for more than two max-sized frame times).

EMAC\_TXEXCESSDEF: Tx Excess Deferral Register - R/NW

Reset = 0x0000 0000

Figure 23-56: EMAC\_TXEXCESSDEF Register Diagram

**Table 23-80:** EMAC\_TXEXCESSDEF Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Tx Pause Frame Register

The EMAC\_TXPAUSEFRM register contains a count of the number of good PAUSE frames transmitted.

**EMAC\_TXPAUSEFRM: Tx Pause Frame Register - R/NW**

Reset = 0x0000 0000

**Figure 23-57:** EMAC\_TXPAUSEFRM Register Diagram

**Table 23-81:** EMAC\_TXPAUSEFRM Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Tx VLAN Frames (Good) Register

The EMAC\_TXVLANFRM\_G register contains a count of the number of good VLAN frames transmitted, exclusive of retried frames.

EMAC\_TXVLANFRM\_G: Tx VLAN Frames (Good) Register - R/NW

Reset = 0x0000 0000

Figure 23-58: EMAC\_TXVLANFRM\_G Register Diagram

Table 23-82: EMAC\_TXVLANFRM\_G Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx Frame Count (Good/Bad) Register

The EMAC\_RXFRMCNT\_GB register contains a count of the number of good and bad frames received.

EMAC\_RXFRMCNT\_GB: Rx Frame Count (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-59: EMAC\_RXFRMCNT\_GB Register Diagram

Table 23-83: EMAC\_RXFRMCNT\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx Octet Count (Good/Bad) Register

The EMAC\_RXOCTCNT\_GB register contains a count of the number of bytes received, exclusive of preamble, in good and bad frames.

EMAC\_RXOCTCNT\_GB: Rx Octet Count (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-60: EMAC\_RXOCTCNT\_GB Register Diagram

Table 23-84: EMAC\_RXOCTCNT\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx Octet Count (Good) Register

The EMAC\_RXOCTCNT\_G register contains a count of the number of bytes received, exclusive of preamble, only in good frames.

EMAC\_RXOCTCNT\_G: Rx Octet Count (Good) Register - R/NW

Reset = 0x0000 0000

Figure 23-61: EMAC\_RXOCTCNT\_G Register Diagram

**Table 23-85:** EMAC\_RXOCTCNT\_G Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx Broadcast Frames (Good) Register

The EMAC\_RXBCASTFRM\_G register contains a count of the number of good broadcast frames received.

**EMAC\_RXBCASTFRM\_G: Rx Broadcast Frames (Good) Register - R/NW**

Reset = 0x0000 0000

**Figure 23-62:** EMAC\_RXBCASTFRM\_G Register Diagram

**Table 23-86:** EMAC\_RXBCASTFRM\_G Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx Multicast Frames (Good) Register

The EMAC\_RXMCASTFRM\_G register contains a count of the number of good multicast frames received.

EMAC\_RXMCASTFRM\_G: Rx Multicast Frames (Good) Register - R/NW

Reset = 0x0000 0000

Figure 23-63: EMAC\_RXMCASTFRM\_G Register Diagram

Table 23-87: EMAC\_RXMCASTFRM\_G Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx CRC Error Register

The EMAC\_RXCRC\_ERR register contains a count of the number of frames received with CRC error.

EMAC\_RXCRC\_ERR: Rx CRC Error Register - R/NW

Reset = 0x0000 0000

Figure 23-64: EMAC\_RXCRC\_ERR Register Diagram

Table 23-88: EMAC\_RXCRC\_ERR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx alignment Error Register

The EMAC\_RXALIGN\_ERR register contains a count of the number of frames received with alignment (dribble) error. Valid only in 10/100 mode.

EMAC\_RXALIGN\_ERR: Rx alignment Error Register - R/NW

Reset = 0x0000 0000

Figure 23-65: EMAC\_RXALIGN\_ERR Register Diagram

Table 23-89: EMAC\_RXALIGN\_ERR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx Runt Error Register

The EMAC\_RXRUNT\_ERR register contains a count of the number of frames received with runt error.

EMAC\_RXRUNT\_ERR: Rx Runt Error Register - R/NW

Reset = 0x0000 0000

Figure 23-66: EMAC\_RXRUNT\_ERR Register Diagram

**Table 23-90:** EMAC\_RXRUNT\_ERR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx Jab Error Register

The EMAC\_RXJAB\_ERR register contains a count of the number of giant frames received with length greater than 1,518 bytes and with CRC error.

**EMAC\_RXJAB\_ERR: Rx Jab Error Register - R/NW**

Reset = 0x0000 0000

**Figure 23-67:** EMAC\_RXJAB\_ERR Register Diagram

**Table 23-91:** EMAC\_RXJAB\_ERR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx Undersize (Good) Register

The EMAC\_RXUSIZE\_G register contains a count of the number of frames received with length less than 64 bytes, without any errors.

EMAC\_RXUSIZE\_G: Rx Undersize (Good) Register - R/NW

Reset = 0x0000 0000

Figure 23-68: EMAC\_RXUSIZE\_G Register Diagram

Table 23-92: EMAC\_RXUSIZE\_G Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx Oversize (Good) Register

The EMAC\_RXOSIZE\_G register contains a count of the number of frames received with length greater than the maxsize, without errors.

EMAC\_RXOSIZE\_G: Rx Oversize (Good) Register - R/NW

Reset = 0x0000 0000

Figure 23-69: EMAC\_RXOSIZE\_G Register Diagram

Table 23-93: EMAC\_RXOSIZE\_G Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx 64-Byte Frames (Good/Bad) Register

The EMAC\_RX64\_GB register contains a count of the number of good and bad frames received with length 64 bytes, exclusive of preamble.

EMAC\_RX64\_GB: Rx 64-Byte Frames (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-70: EMAC\_RX64\_GB Register Diagram

Table 23-94: EMAC\_RX64\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx 65- to 127-Byte Frames (Good/Bad) Register

The EMAC\_RX65TO127\_GB register contains a count of the number of good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble.

EMAC\_RX65TO127\_GB: Rx 65- to 127-Byte Frames (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-71: EMAC\_RX65TO127\_GB Register Diagram

**Table 23-95:** EMAC\_RX65TO127\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx 128- to 255-Byte Frames (Good/Bad) Register

The EMAC\_RX128TO255\_GB register contains a count of the number of good and bad frames received with length between 128 and 255 (inclusive) bytes, exclusive of preamble.

**EMAC\_RX128TO255\_GB: Rx 128- to 255-Byte Frames (Good/Bad) Register - R/NW**

Reset = 0x0000 0000

**Figure 23-72:** EMAC\_RX128TO255\_GB Register Diagram

**Table 23-96:** EMAC\_RX128TO255\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx 256- to 511-Byte Frames (Good/Bad) Register

The EMAC\_RX256TO511\_GB register contains a count of the number of good and bad frames received with length between 256 and 511 (inclusive) bytes, exclusive of preamble.

EMAC\_RX256TO511\_GB: Rx 256- to 511-Byte Frames (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-73: EMAC\_RX256TO511\_GB Register Diagram

Table 23-97: EMAC\_RX256TO511\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx 512- to 1023-Byte Frames (Good/Bad) Register

The EMAC\_RX512TO1023\_GB register contains a count of the number of good and bad frames received with length between 512 and 1023 (inclusive) bytes, exclusive of preamble.

EMAC\_RX512TO1023\_GB: Rx 512- to 1023-Byte Frames (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-74: EMAC\_RX512TO1023\_GB Register Diagram

Table 23-98: EMAC\_RX512TO1023\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx 1024- to Max-Byte Frames (Good/Bad) Register

The EMAC\_RX1024TOMAX\_GB register contains a count of the number of good and bad frames received with length between 1024 and maxsize (inclusive) bytes, exclusive of preamble.

EMAC\_RX1024TOMAX\_GB: Rx 1024- to Max-Byte Frames (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-75: EMAC\_RX1024TOMAX\_GB Register Diagram

Table 23-99: EMAC\_RX1024TOMAX\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx Unicast Frames (Good) Register

The EMAC\_RXUNICASTFRM\_G register contains a count of the number of good unicast frames received.

EMAC\_RXUNICASTFRM\_G: Rx Unicast Frames (Good) Register - R/NW

Reset = 0x0000 0000

Figure 23-76: EMAC\_RXUNICASTFRM\_G Register Diagram

Table 23-100: EMAC\_RXUCASTFRM\_G Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx Length Error Register

The EMAC\_RXLEN\_ERR register contains a count of the number of frames received with length error (Length type field frame size), for all frames with valid length field.

EMAC\_RXLEN\_ERR: Rx Length Error Register - R/NW

Reset = 0x0000 0000

Figure 23-77: EMAC\_RXLEN\_ERR Register Diagram

Table 23-101: EMAC\_RXLEN\_ERR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx Out Of Range Type Register

The EMAC\_RXOORTYPE register contains a count of the number of frames received with length field not equal to the valid frame size (greater than 1,500 but less than 1,536).

EMAC\_RXOORTYPE: Rx Out Of Range Type Register - R/NW

Reset = 0x0000 0000

Figure 23-78: EMAC\_RXOORTYPE Register Diagram

Table 23-102: EMAC\_RXOORTYPE Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx Pause Frames Register

The EMAC\_RXPAUSEFRM register contains a count of the number of good and valid PAUSE frames received.

EMAC\_RXPAUSEFRM: Rx Pause Frames Register - R/NW

Reset = 0x0000 0000

Figure 23-79: EMAC\_RXPAUSEFRM Register Diagram

Table 23-103: EMAC\_RXPAUSEFRM Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx FIFO Overflow Register

The EMAC\_RXFIFO\_OVF register contains a count of the number of missed received frames due to FIFO overflow.

EMAC\_RXFIFO\_OVF: Rx FIFO Overflow Register - R/NW

Reset = 0x0000 0000

Figure 23-80: EMAC\_RXFIFO\_OVF Register Diagram

Table 23-104: EMAC\_RXFIFO\_OVF Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx VLAN Frames (Good/Bad) Register

The EMAC\_RXVLANFRM\_GB register contains a count of the number of good and bad VLAN frames received.

EMAC\_RXVLANFRM\_GB: Rx VLAN Frames (Good/Bad) Register - R/NW

Reset = 0x0000 0000

Figure 23-81: EMAC\_RXVLANFRM\_GB Register Diagram

**Table 23-105:** EMAC\_RXVLANFRM\_GB Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx Watch Dog Error Register

The EMAC\_RXWDOG\_ERR register contains a count of the number of frames received with error due to watchdog timeout error (frames with a data load larger than 2,048 bytes).

**EMAC\_RXWDOG\_ERR: Rx Watch Dog Error Register - R/NW**

Reset = 0x0000 0000

**Figure 23-82:** EMAC\_RXWDOG\_ERR Register Diagram

**Table 23-106:** EMAC\_RXWDOG\_ERR Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

MMC IPC Rx Interrupt Mask Register

The EMAC\_IPC\_RXIMSK register enables (unmasks) MMC IPC receive interrupts.

EMAC\_IPC\_RXIMSK: MMC IPC Rx Interrupt Mask Register - R/W

Reset = 0x0000 0000

Figure 23-83: EMAC\_IPC\_RXIMSK Register Diagram

**Table 23-107:** EMAC\_IPC\_RXIMSK Register Fields

| Bit No. | Bit Name   | Description/Enumeration                                                                                                                                                                                                                  |

## Rx IPv4 Datagrams (Good) Register

The EMAC\_RXIPV4\_GD\_FRM register contains a count of the number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload.

**EMAC\_RXIPV4\_GD\_FRM: Rx IPv4 Datagrams (Good) Register - R/NW**

Reset = 0x0000 0000

**Figure 23-85:** EMAC\_RXIPV4\_GD\_FRM Register Diagram

Table 23-109: EMAC\_RXIPV4\_GD\_FRM Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx IPv4 Datagrams Header Errors Register

The EMAC\_RXIPV4\_HDR\_ERR\_FRM register contains a count of the number of IPv4 datagrams received with header (checksum, length, or version mismatch) errors.

EMAC\_RXIPV4\_HDR\_ERR\_FRM: Rx IPv4 Datagrams Header Errors Register - R/NW

Reset = 0x0000 0000

Figure 23-86: EMAC\_RXIPV4\_HDR\_ERR\_FRM Register Diagram

Table 23-110: EMAC\_RXIPV4\_HDR\_ERR\_FRM Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx IPv4 Datagrams No Payload Frame Register

The EMAC\_RXIPV4\_NOPAY\_FRM register contains a count of the number of IPv4 datagram frames received that did not have a TCP, UDP, or ICMP payload processed by the Checksum engine.

EMAC\_RXIPV4\_NOPAY\_FRM: Rx IPv4 Datagrams No Payload Frame Register - R/NW

Reset = 0x0000 0000

Figure 23-87: EMAC\_RXIPV4\_NOPAY\_FRM Register Diagram

Table 23-111: EMAC\_RXIPV4\_NOPAY\_FRM Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx IPv4 Datagrams Fragmented Frames Register

The EMAC\_RXIPV4\_FRAG\_FRM register contains a count of the number of good IPv4 datagrams with fragmentation.

EMAC\_RXIPV4\_FRAG\_FRM: Rx IPv4 Datagrams Fragmented Frames Register - R/NW

Reset = 0x0000 0000

Figure 23-88: EMAC\_RXIPV4\_FRAG\_FRM Register Diagram

Table 23-112: EMAC\_RXIPV4\_FRAG\_FRM Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx IPv4 UDP Disabled Frames Register

The EMAC\_RXIPV4\_UDSBL\_FRM register contains a count of the number of good IPv4 datagrams received that had a UDP payload with checksum disabled.

EMAC\_RXIPV4\_UDSBL\_FRM: Rx IPv4 UDP Disabled Frames Register - R/NW

Reset = 0x0000 0000

Figure 23-89: EMAC\_RXIPV4\_UDSBL\_FRM Register Diagram

Table 23-113: EMAC\_RXIPV4\_UDSBL\_FRM Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx IPv6 Datagrams Good Frames Register

The EMAC\_RXIPV6\_GD\_FRM register contains a count of the number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads.

EMAC\_RXIPV6\_GD\_FRM: Rx IPv6 Datagrams Good Frames Register - R/NW

Reset = 0x0000 0000

Figure 23-90: EMAC\_RXIPV6\_GD\_FRM Register Diagram

**Table 23-114:** EMAC\_RXIPV6\_GD\_FRM Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx IPv6 Datagrams Header Error Frames Register

The EMAC\_RXIPV6\_HDR\_ERR\_FRM register contains a count of the number of IPv6 datagrams received with header errors (length or version mismatch).

**EMAC\_RXIPV6\_HDR\_ERR\_FRM: Rx IPv6 Datagrams Header Error Frames Register - R/NW**

Reset = 0x0000 0000

**Figure 23-91:** EMAC\_RXIPV6\_HDR\_ERR\_FRM Register Diagram

**Table 23-115:** EMAC\_RXIPV6\_HDR\_ERR\_FRM Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx IPv6 Datagrams No Payload Frames Register

The EMAC\_RXIPV6\_NOPAY\_FRM register contains a count of the number of IPv6 datagram frames received that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers.

EMAC\_RXIPV6\_NOPAY\_FRM: Rx IPv6 Datagrams No Payload Frames Register - R/NW

Reset = 0x0000 0000

Figure 23-92: EMAC\_RXIPV6\_NOPAY\_FRM Register Diagram

Table 23-116: EMAC\_RXIPV6\_NOPAY\_FRM Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx UDP Good Frames Register

The EMAC\_RXUDP\_GD\_FRM register contains a count of the number of good IP datagrams with a good UDP payload. This counter is not updated when the rxipv4\_udtbl\_frms counter is incremented.

EMAC\_RXUDP\_GD\_FRM: Rx UDP Good Frames Register - R/NW

Reset = 0x0000 0000

Figure 23-93: EMAC\_RXUDP\_GD\_FRM Register Diagram

Table 23-117: EMAC\_RXUDP\_GD\_FRM Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx UDP Error Frames Register

The EMAC\_RXUDP\_ERR\_FRM register contains a count of the number of good IP datagrams whose UDP payload has a checksum error.

EMAC\_RXUDP\_ERR\_FRM: Rx UDP Error Frames Register - R/NW

Reset = 0x0000 0000

Figure 23-94: EMAC\_RXUDP\_ERR\_FRM Register Diagram

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx ICMP Good Frames Register

The EMAC\_RXICMP\_GD\_FRM register contains a count of the number of good IP datagrams with a good ICMP payload.

EMAC\_RXICMP\_GD\_FRM: Rx ICMP Good Frames Register - R/NW

Reset = 0x0000 0000

Figure 23-97: EMAC\_RXICMP\_GD\_FRM Register Diagram

Table 23-121: EMAC\_RXICMP\_GD\_FRM Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx ICMP Error Frames Register

The EMAC\_RXICMP\_ERR\_FRM register contains a count of the number of good IP datagrams whose ICMP payload has a checksum error.

EMAC\_RXICMP\_ERR\_FRM: Rx ICMP Error Frames Register - R/NW

Reset = 0x0000 0000

Figure 23-98: EMAC\_RXICMP\_ERR\_FRM Register Diagram

Table 23-122: EMAC\_RXICMP\_ERR\_FRM Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx IPv4 Datagrams Good Octets Register

The EMAC\_RXIPV4\_GD\_OCT register contains a count of the number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data.

EMAC\_RXIPV4\_GD\_OCT: Rx IPv4 Datagrams Good Octets Register - R/NW

Reset = 0x0000 0000

Figure 23-99: EMAC\_RXIPV4\_GD\_OCT Register Diagram

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx IPv4 Datagrams Header Errors Register

The EMAC\_RXIPV4\_HDR\_ERR\_OCT register contains a count of the number of bytes received in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter.

EMAC\_RXIPV4\_HDR\_ERR\_OCT: Rx IPv4 Datagrams Header Errors Register - R/NW

Reset = 0x0000 0000

Figure 23-100: EMAC\_RXIPV4\_HDR\_ERR\_OCT Register Diagram

**Table 23-124:** EMAC\_RXIPV4\_HDR\_ERR\_OCT Register Fields

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

## Rx IPv4 Datagrams No Payload Octets Register

The EMAC\_RXIPV4\_NOPAY\_OCT register contains a count of the number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 headers Length field is used to update this counter.

**EMAC\_RXIPV4\_NOPAY\_OCT: Rx IPv4 Datagrams No Payload Octets Register - R/NW**

Reset = 0x0000 0000

**Figure 23-101:** EMAC\_RXIPV4\_NOPAY\_OCT Register Diagram

| Bit No. | Bit Name | Description/Enumeration |
|---------|----------|-------------------------|
| 31:0    | CNT      | Count Value.            |

Rx IPv4 UDP Disabled Octets Register

The EMAC\_RXIPV4\_UDSBL\_OCT register contains a count of the number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes.

EMAC\_RXIPV4\_UDSBL\_OCT: Rx IPv4 UDP Disabled Octets Register - R/NW

Reset = 0x0000 0000

Figure 23-103: EMAC\_RXIPV4\_UDSBL\_OCT Register Diagram

| 31:0    | CNT      | Count Value.            |

Time Stamp Control Register

The EMAC\_TM\_CTL register controls time stamp generation and update. The EMAC\_TM\_CTL.SNAPTYPSEL, EMAC\_TM\_CTL.TSMSTRENA, and EMAC\_TM\_CTL.TSEVNTENA bits work together to decide the set of PTP packet types for which snapshot needs to be taken. (Encoding shown in table.)

Table 23-137:

| SNAPTYPSEL() | TSMSTRENA | TSEVNTENA | Messages for which snapshot is taken                                                   |
|--------------|-----------|-----------|----------------------------------------------------------------------------------------|
| 00           | X         | 0         | SYNC, Follow_Up, Delay_Req, Delay_Resp                                                 |
| 00           | 0         | 1         | SYNC                                                                                   |
| 00           | 1         | 1         | Delay_Req                                                                              |
| 01           | X         | 0         | SYNC, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp, Pdelay_Resp_Follow_Up |
| 01           | 0         | 1         | SYNC, Pdelay_Req, Pdelay_Resp                                                          |
| 01           | 1         | 1         | Delay_Req, Pdelay_Req, Pdelay_Resp                                                     |
| 10           | X         | X         | SYNC, Delay_Req                                                                        |

**Table 23-137:** (Continued)

| SNAPTYPSEL() | TSMSTRENA | TSEVNTENA | Messages for which snapshot is taken |
|--------------|-----------|-----------|--------------------------------------|
| 11           | X         | X         | Pdelay_Req, Pdelay_Resp              |

**EMAC\_TM\_CTL: Time Stamp Control Register - R/W**

Reset = 0x0000 2000

**Figure 23-113:** EMAC\_TM\_CTL Register Diagram

**Table 23-138:** EMAC\_TM\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                   |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 24      | ATSF     | Auxiliary Time Stamp FIFO Clear.<br>The EMAC_TM_CTL.ATSF bit, when set, resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is cleared, auxiliary snapshots gets stored in the FIFO. |

**Table 23-138:** EMAC\_TM\_CTL Register Fields (Continued)

| Bit No. | Bit Name    | Description/Enumeration                                                                                                                                                                                                                                                                       |
|---------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 18      | TSENMACADDR | Time Stamp Enable MAC Address.<br>The EMAC_TM_CTL.TSENMACADDR bit, when set, uses the DA MAC address (that matches the MAC Address register) to filter the PTP frames when PTP is sent directly over Ethernet.                                                                                |
|         |             | 0      Disable PTP MAC address filter                                                                                                                                                                                                                                                         |
|         |             | 1      Enable PTP MAC address filter                                                                                                                                                                                                                                                          |
| 17:16   | SNAPTYPSEL  | Snapshot Type Select.<br>The EMAC_TM_CTL.SNAPTYPSEL bits along with bit 15 and 14 decide the set of PTP packet types for which snapshot needs to be taken. (See the table in the EMAC_TM_CTL register description.)                                                                           |
| 15      | TSMSTRENA   | Time Stamp Master (Frames) Enable.<br>The EMAC_TM_CTL.TSMSTRENA bit, when set, takes the snapshot for messages relevant to master node only else snapshot is taken for PTP messages relevant to slave node.                                                                                   |
|         |             | 0      Enable Snapshot for Slave Messages                                                                                                                                                                                                                                                     |
|         |             | 1      Enable Snapshot for Master Messages                                                                                                                                                                                                                                                    |
| 14      | TSEVNTENA   | Time Stamp Event (PTP Frames) Enable.<br>The EMAC_TM_CTL.TSEVNTENA bit, when set, takes the time stamp snapshot for PTP event messages only (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When reset, the snapshot is taken for all PTP messages except Announce, Management, and Signaling. |
|         |             | 0      Enable Time Stamp for All Messages                                                                                                                                                                                                                                                     |
|         |             | 1      Enable Time Stamp for Event Messages Only                                                                                                                                                                                                                                              |

**Table 23-138:** EMAC\_TM\_CTL Register Fields (Continued)

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                                                     |
|---------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 13      | TSIPV4ENA | Time Stamp IPV4 (PTP Frames) Enable.<br>The EMAC_TM_CTL.TSIPV4ENA bit, when set, directs the EMAC receiver to process the PTP packets encapsulated in UDP over IPv4 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv4 packets. This bit is set by default. |
|         |           | 0      Disable Time Stamp for PTP Over IPv4 Frames                                                                                                                                                                                                                                          |
|         |           | 1      Enable Time Stamp for PTP Over IPv4 Frames                                                                                                                                                                                                                                           |
| 12      | TSIPV6ENA | Time Stamp IPV6 (PTP Frames) Enable.<br>The EMAC_TM_CTL.TSIPV6ENA bit, when set, directs the EMAC receiver to process PTP packets encapsulated in UDP over IPv6 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv6 packets.                                 |
|         |           | 0      Disable Time Stamp for PTP Over IPv6 frames                                                                                                                                                                                                                                          |
|         |           | 1      Enable Time Stamp for PTP Over IPv6 Frames                                                                                                                                                                                                                                           |
| 11      | TSIPENA   | Time Stamp IP Enable.<br>The EMAC_TM_CTL.TSIPENA bit, when set, directs the EMAC receiver to process the PTP packets encapsulated directly in the Ethernet frames. When this bit is clear, the MAC ignores PTP over Ethernet packets.                                                       |
|         |           | 0      Disable PTP Over Ethernet Frames                                                                                                                                                                                                                                                     |
|         |           | 1      Enable PTP Over Ethernet Frames                                                                                                                                                                                                                                                      |
| 10      | TSVER2ENA | Time Stamp VER2 (Snooping) Enable.<br>The EMAC_TM_CTL.TSVER2ENA bit, when set, processes the PTP packets using the 1588 version 2 format (enables PTP packet snooping for VER2) else processed using the version 1 format.                                                                  |
|         |           | 0      Disable packet snooping for V2 frames                                                                                                                                                                                                                                                |
|         |           | 1      Enable packet snooping for V2 frames                                                                                                                                                                                                                                                 |

**Table 23-138:** EMAC\_TM\_CTL Register Fields (Continued)

| Bit No. | Bit Name  | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                |
|---------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9       | TSCTRLSSR | Time Stamp Control Nanosecond Rollover.<br>The EMAC_TM_CTL.TSCTRLSSR bit, when set, rolls over the Time Stamp nanoseconds register after 0x3B9A_C9FF value ( $10^9-1$ ) and increments the time stamp (low) seconds. When reset, the roll over value of nanosecond register is 0x7FFF_FFFF. The nanosecond increment has to be programmed correctly depending on the PTP reference clock frequency and this bit value. |
|         |           | 0      Roll Over Nanosecond After 0x7FFFFFFF                                                                                                                                                                                                                                                                                                                                                                           |
|         |           | 1      Roll Over Nanosecond After 0x3B9AC9FF                                                                                                                                                                                                                                                                                                                                                                           |
| 8       | TSENALL   | Time Stamp Enable All (Frames).<br>The EMAC_TM_CTL.TSENALL bit, when set, enables the time stamp snapshot for all frames received by the core.                                                                                                                                                                                                                                                                         |
|         |           | 0      Disable timestamp for all frames                                                                                                                                                                                                                                                                                                                                                                                |
|         |           | 1      Enable timestamp for all frames                                                                                                                                                                                                                                                                                                                                                                                 |
| 5       | TSADDREG  | Time Stamp Addend Register Update.<br>The EMAC_TM_CTL.TSADDREG bit, when set, updates the contents of the Time Stamp Addend register in the PTP block for fine correction. This bit is cleared when the update is completed. This bit should be zero before setting it.                                                                                                                                                |
| 4       | TSTRIG    | Time Stamp (Target Time) Trigger Enable.<br>The EMAC_TM_CTL.TSTRIG bit, when set, generates the time stamp interrupt when the System Time becomes greater than the value written in Target Time register. This bit is reset after the generation of the Time Stamp Trigger Interrupt.                                                                                                                                  |
|         |           | 1      Interrupt (TS) if system time is greater than target time register                                                                                                                                                                                                                                                                                                                                              |

**Table 23-138:** EMAC\_TM\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3       | TSUPDT   | Time Stamp (System Time) Update.<br>The EMAC_TM_CTL.TSUPDT bit, when set, updates (adds/subtracts) the system time with the value specified in System Time - Seconds Update Register and System Time - Nanoseconds Update Register. This register bit should be read zero before updating it. This bit is reset once the update is completed in hardware. The "Time Stamp Higher Word" register is not updated.          |
|         |          | 1 System time updated with Time stamp register values                                                                                                                                                                                                                                                                                                                                                                    |
| 2       | TSINIT   | Time Stamp (System Time) Initialize.<br>The EMAC_TM_CTL.TSINIT bit, when set, initializes (over-writes) the system time with the value specified in the System Time - Seconds Update Register and System Time - Nanoseconds Update Register. This register bit should be read zero before updating it. This bit is reset once the initialize is complete. The "Time Stamp Higher Word" register can only be initialized. |
|         |          | 1 System time initialized with Time stamp register values                                                                                                                                                                                                                                                                                                                                                                |
| 1       | TSCFUPDT | Time Stamp (System Time) Fine/Coarse Update.<br>The EMAC_TM_CTL.TSCFUPDT bit, when set, indicates that the system times update to be done using fine correction method. When reset, it indicates the system time stamp correction to be done using Coarse method.                                                                                                                                                        |
|         |          | 0 Use Coarse Correction Method for System Time Update                                                                                                                                                                                                                                                                                                                                                                    |
|         |          | 1 Use Fine Correction Method for System Time Update                                                                                                                                                                                                                                                                                                                                                                      |

Table 23-138: EMAC\_TM\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                          |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0       | TSENA    | Time Stamp (PTP) Enable.<br>The EMAC_TM_CTL.TSENA bit, when set, enables PTP module for timestamping transmitted and received frames. It also enables System Time which will be used for timestamping the frames. User should initialize the System Time after setting this bit. |
|         |          | 0      Disable PTP Module                                                                                                                                                                                                                                                        |
|         |          | 1      Enable PTP Module                                                                                                                                                                                                                                                         |

Time Stamp Sub Second Increment Register

The EMAC\_TM\_SUBSEC register contains the value by which the sub second is incremented.

EMAC\_TM\_SUBSEC: Time Stamp Sub Second Increment Register - R/W

Reset = 0x0000 0000

Figure 23-114: EMAC\_TM\_SUBSEC Register Diagram

Table 23-139: EMAC\_TM\_SUBSEC Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | SSINC    | Sub-Second Increment Value.<br>The value in the EMAC_TM_SUBSEC.SSINC bits is accumulated every PTP clock cycle with the contents of the nanosecond register. For example, when PTP clock is 50 MHz (period is 20 ns), the processor should program 20 (0x14) when the Time Stamp Nanoseconds register has an accuracy of 1 ns (TSCTRLSSR bit is set). When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465ns. In this case, the processor should program a value of 43 (0x2B) that is derived by 20ns/0.465. |

## Time Stamp Low Seconds Register

The EMAC\_TM\_SEC register contains the lower 32 bits of the seconds field of the system time.

EMAC\_TM\_SEC: Time Stamp Low Seconds Register - R/W

Reset = 0x0000 0000

Figure 23-115: EMAC\_TM\_SEC Register Diagram

Table 23-140: EMAC\_TM\_SEC Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                            |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | TSS      | Time Stamp Second.<br>The value in the EMAC_TM_SEC.TSS bit field indicates the current value in seconds of the System Time maintained by the core. |

## Time Stamp Nano Seconds Register

The EMAC\_TM\_NSEC register contains the nano-seconds field of the system time.

EMAC\_TM\_NSEC: Time Stamp Nano Seconds Register - R/W

Reset = 0x0000 0000

Figure 23-116: EMAC\_TM\_NSEC Register Diagram

Table 23-141: EMAC\_TM\_NSEC Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                  |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 30:0    | TSSS     | Time Stamp Nanoseconds.<br>The value in the EMAC_TM_NSEC.TSSS bit field has the nanosecond representation of time, with an accuracy of 0.46 nano-second. (When TSCTRLSSR is set, each bit represents 1 ns and the maximum value will be 0x3B9A_C9FF, after which it rolls-over to zero). |

Time Stamp Seconds Update Register

The EMAC\_TM\_SECUPDT register contains the low 32 bits to be added to, subtracted from, or written to the seconds field of the system time.

EMAC\_TM\_SECUPDT: Time Stamp Seconds Update Register - R/W

Reset = 0x0000 0000

Figure 23-117: EMAC\_TM\_SECUPDT Register Diagram

Table 23-142: EMAC\_TM\_SECUPDT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                          |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | TSS      | Time Stamp Second Initialize/Update.<br>The value in the EMAC_TM_SECUPDT.TSS bit field indicates the time, in seconds, to be initialized or added to or subtracted from the system time seconds. |

Time Stamp Nano Seconds Update Register

The EMAC\_TM\_NSECUPDT register contains the low 32 bits to be added to, subtracted from, or written to the nano-seconds field of the system time.

EMAC\_TM\_NSECUPDT: Time Stamp Nano Seconds Update Register - R/W

Reset = 0x0000 0000

Figure 23-118: EMAC\_TM\_NSECUPDT Register Diagram

Table 23-143: EMAC\_TM\_NSECUPDT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                 |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31      | ADDSUB   | Add or Subtract the Time.<br>The EMAC_TM_NSECUPDT .ADDSUB bit, when set, subtracts the time value with the contents of the update registers. When this bit is reset, the time value is added with the contents of the update registers. |
| 30:0    | TSSS     | Time Stamp Sub Second Initialize/Increment.<br>The value in the EMAC_TM_NSECUPDT .TSSS bit field indicates the time, in nanoseconds, to be initialized or added to or subtracted from the system time nanoseconds.                      |

Time Stamp Addend Register

The EMAC\_TM\_ADDEND register lets software adjust the clock frequency linearly to match the master clock frequency.

EMAC\_TM\_ADDEND: Time Stamp Addend Register - R/W

Reset = 0x0000 0000

Figure 23-119: EMAC\_TM\_ADDEND Register Diagram

Table 23-144: EMAC\_TM\_ADDEND Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                             |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | TSAR     | Time Stamp Addend Register.<br>The EMAC_TM_ADDEND.TSAR bits indicate the 32-bit time value to be added to the Accumulator register to achieve time synchronization. |

Time Stamp Target Time Seconds Register

The EMAC\_TM\_TGTM register contains the high 32 bits of the target seconds field for comparison to the corresponding system time field.

EMAC\_TM\_TGTM: Time Stamp Target Time Seconds Register - R/W

Reset = 0x0000 0000

Figure 23-120: EMAC\_TM\_TGTM Register Diagram

**Table 23-145:** EMAC\_TM\_TGTM Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                             |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | TSTR     | Target Time Seconds Register.<br>The EMAC_TM_TGTM.TSTR bit field stores the time in seconds. When the time stamp value matches or exceeds both Target Time Stamp registers, then based on the bits 6:5 (TRGTMODSEL) of PPS Control Register, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled). |

## Time Stamp Target Time Nano Seconds Register

The EMAC\_TM\_NTGMTM register contains the high 32 bits of the target nano-seconds field for comparison to the corresponding system time field.

**EMAC\_TM\_NTGMTM: Time Stamp Target Time Nano Seconds Register - R/W**

Reset = 0x0000 0000

**Figure 23-121:** EMAC\_TM\_NTGMTM Register Diagram

**Table 23-146:** EMAC\_TM\_NTGMTM Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31      | TSTRBUSY | Target Time Register Busy.<br>The EMAC_TM_NTGMTM.TSTRBUSY bit is set when Flexible PPS is enabled and the PPSCCTL field (bit 3:0) in PPS Control Register is programmed to 0001, 0010 or 0100. Programming the PPSCCTL field to 0001, 0010 or 0100, instructs the core to synchronize the Target Time Registers to the PTP clock domain. The EMAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain. The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. |

Table 23-146: EMAC\_TM\_NTGTM Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 30:0    | TSTR     | Target Time Nano Seconds.<br>The EMAC_TM_NTGTM.TSTR bit field stores the time in (signed) nanoseconds. When the value of the time stamp matches the both Target Time Stamp registers, then based on the TRGTMODSEL field (bits 6:5) in PPS Control Register, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled). This value should not exceed 0x3B9A_C9FF when TSCTRLSSR is set in the Timestamp control register. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. |

Time Stamp High Second Register

The EMAC\_TM\_HISEC register contains the upper 32 bits of the seconds field of the system time.

EMAC\_TM\_HISEC: Time Stamp High Second Register - R/W

Reset = 0x0000 0000

Figure 23-122: EMAC\_TM\_HISEC Register Diagram

Table 23-147: EMAC\_TM\_HISEC Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                        |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0    | TSHWR    | Time Stamp Higher Word Seconds Register.<br>The EMAC_TM_HISEC.TSHWR bit field contains the most significant 16-bits of the time stamp seconds value. The register is directly written to initialize the value. This register is incremented when there is an overflow from the 32-bits of the Time Stamp Low Seconds register. |

## Time Stamp Status Register

The EMAC\_TM\_STMPSTAT register contains the PTP status.

### EMAC\_TM\_STMPSTAT: Time Stamp Status Register - R/W

Reset = 0x0000 0000

**Figure 23-123:** EMAC\_TM\_STMPSTAT Register Diagram

|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1       | TSTARGET | Time Stamp Target Time Reached.<br>The EMAC_TM_STMPSTAT.TSTARGET bit, when set, indicates the value of system time has reached or passed the value specified in the Target Time Seconds and Nanoseconds registers |
| 0       | TSSOVF   | Time Stamp Seconds Overflow.<br>The EMAC_TM_STMPSTAT.TSSOVF bit, when set, indicates that the seconds value of the time stamp (when supporting PTP version 2 format) has overflowed beyond 32'hFFFF_FFFF.         |

## PPS Control Register

The EMAC\_TM\_PPSCCTL register controls the interval of PPS output.

When the EMAC\_TM\_PPSCCTL.PPSEN bit is disabled (=0, fixed PPS output), the EMAC\_TM\_PPSCCTL.PPSCCTL bits control the behavior of the PPS output signal. The default value of PPSCCTL is 0000 and the PPS output is 1 pulse every second. For other values of PPSCCTL, the PPS output becomes a generated clock. (See bit enumerations for frequencies.) In the binary rollover mode, the PPS output has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. This behavior is because of the non-linear toggling of the bits in the digital rollover mode in System Time - Nanoseconds Register.

When the EMAC\_TM\_PPSCCTL.PPSEN bit is enabled (=1, flexible PPS output), the EMAC\_TM\_PPSCCTL.PPSCCTL bits function as PPSCMD. (See bit enumerations for commands.) Programming these bits with a non-zero value instructs the core to initiate an event. After the command is transferred or synchronized to the PTP clock domain, these bits gets cleared automatically. Software should ensure that these bits are programmed only when they are "all-zero".

- EMAC\_TM\_PPSCCTL.PPSCCTL=0000 CMD=No Command (PPS output =1Hz)
- EMAC\_TM\_PPSCCTL.PPSCCTL=0001  
(CMD=START Single; BR=2kHz; DR=1kHz) This PPS command generates single pulse rising at start point defined in Target Time Registers and of duration defined in PPS Width Register. (Binary Rollover = 2 kHz; Digital Rollover = 1 kHz.)
- EMAC\_TM\_PPSCCTL.PPSCCTL=0010  
(CMD=START Pulse; BR=4kHz; DR=2kHz) This PPS command generates the train of pulses rising at the start point defined in the Target Time Registers and of duration defined in the PPS Width Register

and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by 'STOP Pulse train at time' or 'STOP Pulse Train immediately' commands. (Binary Rollover = 4 kHz; Digital Rollover = 2 kHz.)

- EMAC\_TM\_PPSCTL.PPSCTL=0011

(CMD=Cancel START; BR=8kHz; DR=4kHz) This PPS command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. (Binary Rollover = 4 kHz; Digital Rollover = 4 kHz.)

- EMAC\_TM\_PPSCTL.PPSCTL=0100

(CMD=STOP Pulse Time; BR=16kHz; DR=8kHz) This PPS command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. (Binary Rollover = 16 kHz; Digital Rollover = 8 kHz.)

- EMAC\_TM\_PPSCTL.PPSCTL=0101

(CMD=STOP Pulse Now) This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010).

- EMAC\_TM\_PPSCTL.PPSCTL=0110

(CMD=Cancel STOP Pulse) This PPS command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command.

All values not shown in the bit enumerations are reserved.

**Table 23-152:** EMAC\_TM\_PPSINTVL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | PPSINT   | PPS Output Signal Interval.<br>The EMAC_TM_PPSINTVL.PPSINT bits store the interval between the rising edges of PPS signal output in terms of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20ns), and desired interval between rising edges of PPS signal output is 100ns (that is, 5 units of sub-second increment value), then you should program value 4 (5-1) in this register. |

## PPS Width Register

The EMAC\_TM\_PPSWIDTH register contains the interval value for the time between a rising and the next falling edge (width) of PPS output.

EMAC\_TM\_PPSWIDTH: PPS Width Register - R/W

Reset = 0x0000 0000

Figure 23-128: EMAC\_TM\_PPSWIDTH Register Diagram

Table 23-153: EMAC\_TM\_PPSWIDTH Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | PPSINT   | PPS Output Signal Interval.<br>The EMAC_TM_PPSWIDTH.PPSINT bits store the interval between the rising edges of PPS signal output in terms of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20ns), and desired interval between rising edges of PPS signal output is 100ns (that is, 5 units of sub-second increment value), then you should program value 4 (5-1) in this register. |

DMA Bus Mode Register

The EMAC\_DMA\_BUSMODE register selects the DMA bus operating modes for EMAC DMA.

**EMAC\_DMA\_BUSMODE: DMA Bus Mode Register - R/W**

Reset = 0x0002 0101

**Figure 23-129: EMAC\_DMA\_BUSMODE Register Diagram**

**Table 23-154: EMAC\_DMA\_BUSMODE Register Fields**

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                          |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 25      | AAL      | Address Aligned Bursts.<br>The EMAC_DMA_BUSMODE.AAL bit, when set high and the FB bit equals 1, directs the SCB interface to generate all bursts aligned to the start address LS bits. If the FB bit is equal to 0, the first burst (accessing the data buffers start address) is not aligned, but subsequent bursts are aligned to the address. |
| 24      | PBL8     | PBL * 8.<br>The EMAC_DMA_BUSMODE.PBL8 bit, when set high, multiplies the PBL value programmed (bits [22:17] and bits [13:8]) eight times. Therefore, the DMA transfers the data in 8, 16, and 32 beats depending on the PBL value.                                                                                                               |
| 23      | USP      | Use Separate PBL.<br>The EMAC_DMA_BUSMODE.USP bit, when set high, configures the RxDMA to use the value configured in bits [22:17] as PBL while the PBL value in bits [13:8] is applicable to TxDMA operations only.                                                                                                                             |

**Table 23-154:** EMAC\_DMA\_BUSMODE Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 22:17   | RPBL     | <p>Receive Programmable Burst Length.</p> <p>The EMAC_DMA_BUSMODE . RPBL bits indicate the maximum number of beats to be transferred in one RxDMA transaction. This is the maximum value that is used in a single block Read/Write. The RxDMA always attempts to burst as specified in RPBL every time it starts a Burst transfer on the host bus. RPBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. These bits are valid and applicable only when USP is set high.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 16      | FB       | <p>Fixed Burst.</p> <p>The EMAC_DMA_BUSMODE . FB bit controls whether the SCB Master interface performs fixed burst transfers or not. See bit 0 (UNDEF: SCB Undefined Burst Length) of the SCB Bus Mode register for detailed description.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 13:8    | PBL      | <p>Programmable Burst Length.</p> <p>The EMAC_DMA_BUSMODE . PBL bits indicate the maximum number of beats to be transferred in one DMA transaction. This will be the maximum value that is used in a single block Read/Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable for TxDMA transactions only.</p> <p>PBL-max limit = (FIFO size / 2) / 4.<br/> PBL-max limit (transmit) = 256 bytes / 2 / 4 = 32.<br/> PBL-max limit (receive) = 128 bytes / 2 / 4 = 16.</p> <p>Note that this PBL is at the DMA end. If PBL= 32 and if BLEN16 is enabled, the DMA automatically splits 32 bursts in to 2 x 16 bursts. If PBL = 8, and if BLEN16 is enabled, the max burst is limited to BLEN8. If PBL8 bit in DMA_BUSMODE register is set, the programmed PBL value is multiplied by 8 times internally. However, the result cannot be more than the above maximum limits specified above.</p> |

**Table 23-154:** EMAC\_DMA\_BUSMODE Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7       | ATDS     | <p>Alternate Descriptor Size.</p> <p>The <code>EMAC_DMA_BUSMODE.ATDS</code> bit, when set, increases the size of the alternate descriptor to 32 bytes (8 DWORDS). This is required when the Advanced Time Stamp feature or Full IPC Offload Engine is enabled in the receiver. When reset, the descriptor size reverts back to 4 DWORDS (16 bytes). The enhanced descriptor is not required if the Advanced Time Stamp and IPC Full Checksum Offload features are not enabled. In such case, you can use the 16 bytes descriptor to save 4 bytes of memory.</p>                                                               |
| 6:2     | DSL      | <p>Descriptor Skip Length.</p> <p>The <code>EMAC_DMA_BUSMODE.DSL</code> bit specifies the number of 32-bit words to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When DSL value is equal to zero, then the descriptor table is taken as contiguous by the DMA, in Ring mode.</p>                                                                                                                                                                                                                                                   |
| 0       | SWR      | <p>Software Reset.</p> <p>The <code>EMAC_DMA_BUSMODE.SWR</code> bit, when set, directs the MAC DMA Controller to reset all MAC Subsystem internal registers and logic. It is cleared automatically after the reset operation has completed in all of the core clock domains. Read a 0 value in this bit before re-programming any register of the core. Note: The reset operation is completed only when all the resets in all the active clock domains are de-asserted. Therefore, it is essential that all the PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion.</p> |

## DMA Tx Poll Demand Register

The `EMAC_DMA_TXPOLL` register directs the EMAC to poll the transmit descriptor list.

EMAC\_DMA\_TXPOLL: DMA Tx Poll Demand Register - R/W

Reset = 0x0000 0000

Figure 23-130: EMAC\_DMA\_TXPOLL Register Diagram

Table 23-155: EMAC\_DMA\_TXPOLL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | START    | Transmit Poll Demand.<br>The EMAC_DMA_TXPOLL . START bits, when written with any value, cause the DMA to read the current descriptor pointed to by Transmit Current Descriptor register. If that descriptor is not available (owned by application), transmission returns to the Suspend state and DMA Status register[2](Transmit buffer unavailable bit) is asserted. If the descriptor is available, transmission resumes. |

DMA Rx Poll Demand register

The EMAC\_DMA\_RXPOLL register directs the EMAC to poll the receive descriptor list.

EMAC\_DMA\_RXPOLL: DMA Rx Poll Demand register - R/W

Reset = 0x0000 0000

Figure 23-131: EMAC\_DMA\_RXPOLL Register Diagram

**Table 23-156:** EMAC\_DMA\_RXPOLL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | START    | Receive Poll Demand.<br>The EMAC_DMA_RXPOLL . START bits, when written with any value, cause the DMA to read the current descriptor pointed to by Receive Current Descriptor register. If that descriptor is not available (owned by application), reception returns to the Suspended state and DMA Status register[7](Receive buffer unavailable bit) is asserted. If the descriptor is available, the Receive DMA returns to the active state. |

## DMA Rx Descriptor List Address Register

The EMAC\_DMA\_RXDSC\_ADDR register holds the address for the DMA receive descriptor list. Writing to this Register is permitted only when reception is stopped. When stopped, this must be written to before the receive Start command is given. The processor can write to DMA\_RXDSC\_ADDR only when Rx DMA has stopped (bit 1, SR, =0 in Operation Mode Register). When stopped, it can be written with a new descriptor list address. When the processor sets the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                   |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | VALUE    | Start of Receive List.<br>The EMAC_DMA_RXDSC_ADDR.VALUE bit field contains the base address of the First Descriptor in the Receive Descriptor list. The LSB bits [1:0] for the 32bit bus width are ignored and are taken as all-zero by the DMA internally. Therefore, these LSB bits are Read-Only (RO). |

## DMA Tx Descriptor List Address Register

The EMAC\_DMA\_TXDSC\_ADDR register holds the address for the DMA transmit descriptor list. The processor can write to this Register only when Tx DMA has stopped (bit 13, ST, =0 in Operation Mode Register). When stopped, this can be written with a new descriptor list address. When the processor sets the ST bit to 1, the DMA takes the newly programmed descriptor base address. If this Register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

|         |          | 7 Running: Transferring RX packet data from RX buffer to host memory                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 16      | NIS      | Normal Interrupt Summary.<br>The value of the EMAC_DMA_STAT.NIS bit field is the logical OR of the following when the corresponding interrupt bits are enabled in DMA Interrupt Enable Register: EMAC_DMA_STAT.TI, EMAC_DMA_STAT.TU, EMAC_DMA_STAT.RI, and EMAC_DMA_STAT.ERI. Only unmasked bits affect the Normal Interrupt Summary bit. This is a sticky bit and must be cleared (by writing a 1 to this bit) each time a corresponding bit that causes NIS to be set is cleared.                                                                |
| 15      | AIS      | Abnormal Interrupt Summary.<br>The value of the EMAC_DMA_STAT.AIS bit field is the logical OR of the following when the corresponding interrupt bits are enabled in DMA Interrupt Enable Register: EMAC_DMA_IEN.TPS, EMAC_DMA_IEN.TJT, EMAC_DMA_IEN.OVF, EMAC_DMA_IEN.UNF, EMAC_DMA_IEN.RU, EMAC_DMA_IEN.RPS, EMAC_DMA_IEN.RWT, EMAC_DMA_IEN.ETI, and EMAC_DMA_IEN.FBI. Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit that causes AIS to be set is cleared. |

**Table 23-159:** EMAC\_DMA\_STAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14      | ERI      | Early Receive Interrupt.<br>The EMAC_DMA_STAT.ERI bit indicates that the DMA had filled the first data buffer of the packet. RI bit of this register automatically clears this bit.                                                                                                                                                                                                                                                                                                                                                                            |
| 13      | FBI      | Fatal Bus Error Interrupt.<br>The EMAC_DMA_STAT.FBI bit indicates that a bus error occurred, as detailed in [25:23]. When this bit is set, the corresponding DMA engine disables all its bus accesses.                                                                                                                                                                                                                                                                                                                                                         |
| 10      | ETI      | Early Transmit Interrupt.<br>The EMAC_DMA_STAT.ETI bit indicates that the frame to be transmitted was fully transferred to the MFL Transmit FIFO.                                                                                                                                                                                                                                                                                                                                                                                                              |
| 9       | RWT      | Receive WatchDog Timeout.<br>The EMAC_DMA_STAT.RWT bit is asserted when a frame with a length greater than 2,048 bytes is received (10, 240 when Jumbo Frame mode is enabled).                                                                                                                                                                                                                                                                                                                                                                                 |
| 8       | RPS      | Receive Process Stopped.<br>The EMAC_DMA_STAT.RPS bit is asserted when the Receive Process enters the Stopped state.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 7       | RU       | Receive Buffer Unavailable.<br>The EMAC_DMA_STAT.RU bit indicates that the Next Descriptor in the Receive List is owned by the application and cannot be acquired by the DMA. Receive Process is suspended. To resume processing Receive descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor was owned by the DMA. |
| 6       | RI       | Receive Interrupt.<br>The EMAC_DMA_STAT.RI bit indicates the completion of frame reception. Specific frame status information has been posted in the descriptor. Reception remains in the Running state.                                                                                                                                                                                                                                                                                                                                                       |
| 5       | UNF      | Transmit Buffer Underflow.<br>The EMAC_DMA_STAT.UNF bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.                                                                                                                                                                                                                                                                                                                                                       |

**Table 23-159:** EMAC\_DMA\_STAT Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4       | OVF      | Receive Buffer Overflow.<br>The <code>EMAC_DMA_STAT.OVF</code> bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to application, the overflow status is set in <code>RDES0[11]</code> .                                                                                                                                                                                                |
| 3       | TJT      | Transmit Jabber Timeout.<br>The <code>EMAC_DMA_STAT.TJT</code> bit indicates that the Transmit Jabber Timer expired, meaning that the transmitter had been excessively active. The transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout <code>TDES0[14]</code> flag to assert.                                                                                                                     |
| 2       | TU       | Transmit Buffer Unavailable.<br>The <code>EMAC_DMA_STAT.TU</code> bit indicates that the Next Descriptor in the Transmit List is owned by the application and cannot be acquired by the DMA. Transmission is suspended. Bits[22:20] explain the Transmit Process state transitions. To resume processing transmit descriptors, the application should change the ownership of the bit of the descriptor and then issue a Transmit Poll Demand command. |
| 1       | TPS      | Transmit Process Stopped.<br>The <code>EMAC_DMA_STAT.TPS</code> bit is set when the transmission is stopped.                                                                                                                                                                                                                                                                                                                                           |
| 0       | TI       | Transmit Interrupt.<br>The <code>EMAC_DMA_STAT.TI</code> bit indicates that frame transmission is finished and <code>TDES1[31]</code> is set in the First Descriptor.                                                                                                                                                                                                                                                                                  |

## DMA Operation Mode Register

The `EMAC_DMA_OPMODE` register selects receive and transmit DMA operating modes.

**EMAC\_DMA\_OPMODE: DMA Operation Mode Register - R/W**

Reset = 0x0000 0000

**Figure 23-135:** EMAC\_DMA\_OPMODE Register Diagram

**Table 23-160:** EMAC\_DMA\_OPMODE Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 26      | DT       | Disable Dropping TCP/IP Errors.<br>The EMAC_DMA_OPMODE.DT bit, when set, directs the core not to drop frames that only have errors detected by the Receive Checksum Offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors in the encapsulated payload only. When this bit is reset, all error frames are dropped if the FEF bit is reset. |
| 25      | RSF      | Receive Store and Forward.<br>The EMAC_DMA_OPMODE.RSF bit, when set, directs the MFL only to read a frame from the Rx FIFO after the complete frame has been written to it, ignoring RTC bits. When this bit is reset, the Rx FIFO operates in threshold mode, subject to the threshold specified by the RTC bits.                                                                                                     |

**Table 23-160:** EMAC\_DMA\_OPMODE Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 24      | DFF      | <p>Disable Flushing of received Frames.</p> <p>The EMAC_DMA_OPMODE.DFF bit, when set, directs the RxDMA not to flush any frames because of the unavailability of receive descriptors/buffers as it does normally when this bit is reset.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 21      | TSF      | <p>Transmit Store and Forward.</p> <p>The EMAC_DMA_OPMODE.TSF bit, when set, starts transmission when a full frame resides in the MFL Transmit FIFO. When this bit is set, the TTC values specified in Register 6[16:14] are ignored. This bit should be changed only when transmission is stopped.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 20      | FTF      | <p>Flush Transmit FIFO.</p> <p>The EMAC_DMA_OPMODE.FTF bit, when set, directs the transmit FIFO controller logic to reset to its default values and thus all data in the Tx FIFO is lost/flushed. This bit is cleared internally when the flushing operation is completed fully. The Operation Mode register should not be written to until this bit is cleared. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt frame transmission. Note: The flush operation completes only after emptying the TxFIFO of its contents and all the pending Transmit Status of the transmitted frames are accepted by the host. In order to complete this flush operation, the PHY transmit clock is required to be active.</p> |

**Table 23-160:** EMAC\_DMA\_OPMODE Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                              |
|---------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16:14   | TTC      | <p>Transmit Threshold Control.</p> <p>The EMAC_DMA_OPMODE.TTC bits control the threshold level of the MFL Transmit FIFO. Transmission starts when the frame size within the MFL Transmit FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are also transmitted. These bits are used only when the TSF bit (Bit 21) is reset. "011" is not used.</p> |
|         |          | 0 64                                                                                                                                                                                                                                                                                                                                                                                                 |
|         |          | 1 128                                                                                                                                                                                                                                                                                                                                                                                                |

**Table 23-160:** EMAC\_DMA\_OPMODE Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 13      | ST       | <p>Start/Stop Transmission.</p> <p>The EMAC_DMA_OPMODE.ST bit, when set, places transmission in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Transmit Descriptor List Address, or from the position retained when transmission was stopped previously. If the current descriptor is not owned by the DMA, transmission enters the Suspended state and Transmit Buffer Unavailable (DMA Status register[2]) is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting Transmit Descriptor List Address register, then the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and becomes the current position when transmission is restarted. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state.</p> |
| 7       | FEF      | <p>Forward Error Frames.</p> <p>The EMAC_DMA_OPMODE.FEF bit, when reset, directs the Rx FIFO to drop frames with error status (CRC error, collision error, giant frame, watchdog timeout, overflow). However, if the frames start byte (write) pointer is already transferred to the read controller side (in Threshold mode), then the frames are not dropped. When FEF bit is set, all frames except runt error frames are forwarded to the DMA. But when Rx FIFO overflows when a partial frame is written, then such frames are dropped even when FEF is set.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 6       | FUF      | <p>Forward Undersized good Frames.</p> <p>The EMAC_DMA_OPMODE.FUF bit, when set, directs the Rx FIFO to forward Undersized frames (frames with no Error and length less than 64 bytes) including pad-bytes and CRC). When reset, the Rx FIFO drops all frames of less than 64 bytes, unless it is already transferred because of lower value of Receive Threshold (e.g., RTC = 01).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 23-160:** EMAC\_DMA\_OPMODE Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4:3     | RTC      | Receive Threshold Control.<br>The EMAC_DMA_OPMODE.RTC bits control the threshold level of the MFL Receive FIFO. Transfer (request) to DMA starts when the frame size within the MFL Receive FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are transferred automatically. These bits are valid only when the RSF bit is zero, and are ignored when the RSF bit is set to 1. "11" is not used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|         |          | 0 64                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|         |          | 1 32                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|         |          | 2 96                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|         |          | 3 128                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 2       | OSF      | Operate on Second Frame.<br>The EMAC_DMA_OPMODE.OSF bit, when set, instructs the DMA to process a second frame of Transmit data even before status for first frame is obtained.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 1       | SR       | Start/Stop Receive.<br>The EMAC_DMA_OPMODE.SR bit, when set, places the Receive process in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes incoming frames. Descriptor acquisition is attempted from the current position in the list, which is the address set by DMA Receive Descriptor List Address or the position retained when the Receive process was previously stopped. If no descriptor is owned by the DMA, reception is suspended and Receive Buffer Unavailable (DMA Status Register[7]) is set. The Start Receive command is effective only when reception has stopped. If the command was issued before setting DMA Receive Descriptor List Address Register, DMA behavior is unpredictable. When this bit is cleared, RxDMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state. |

## DMA Interrupt Enable Register

The EMAC\_DMA\_IEN register enables (unmasks) EMAC DMA interrupts.

**EMAC\_DMA\_IEN: DMA Interrupt Enable Register - R/W**

Reset = 0x0000 0000

**Figure 23-136:** EMAC\_DMA\_IEN Register Diagram

**Table 23-161:** EMAC\_DMA\_IEN Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                       |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16      | NIS      | Normal Interrupt Summary Enable.<br>The EMAC_DMA_IEN.NIS bit, when set, enables a normal interrupt. When this bit is reset, a normal interrupt is disabled. This bit enables the following bits: EMAC_DMA_STAT.TI, EMAC_DMA_STAT.TU, EMAC_DMA_STAT.RI, and EMAC_DMA_STAT.ERI. |

**Table 23-161:** EMAC\_DMA\_IEN Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                             |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15      | AIS      | Abnormal Interrupt Summary Enable.<br>The EMAC_DMA_IEN.AIS bit, when set, enables an abnormal interrupt. When this bit is reset, an Abnormal Interrupt is disabled. This bit enables the following bits: EMAC_DMA_STAT.TPS, EMAC_DMA_STAT.TJT, EMAC_DMA_STAT.OVF, EMAC_DMA_STAT.RU, EMAC_DMA_STAT.RPS, EMAC_DMA_STAT.RWT, EMAC_DMA_STAT.ETI, and EMAC_DMA_STAT.FBI. |
| 14      | ERI      | Early Receive Interrupt Enable.<br>The EMAC_DMA_IEN.ERI bit, when set with Normal Interrupt Summary Enable in this register, enables the Early Receive Interrupt. When this bit is reset, Early Receive Interrupt is disabled.                                                                                                                                      |
| 13      | FBI      | Fatal Bus Error Enable.<br>The EMAC_DMA_IEN.FBI bit, when set with Abnormal Interrupt Summary Enable in this register, enables the Fatal Bus Error Interrupt. When this bit is reset, Fatal Bus Error Enable Interrupt is disabled.                                                                                                                                 |
| 10      | ETI      | Early Transmit Interrupt Enable.<br>The EMAC_DMA_IEN.ETI bit, when this bit is set with an Abnormal Interrupt Summary Enable in this register, enables the Early Transmit Interrupt. When this bit is reset, Early Transmit Interrupt is disabled.                                                                                                                  |
| 9       | RWT      | Receive Watchdog Timeout Enable.<br>The EMAC_DMA_IEN.RWT bit, when set with Abnormal Interrupt Summary Enable in this register, enables the Receive Watchdog Timeout Interrupt. When this bit is reset, Receive Watchdog Timeout Interrupt is disabled.                                                                                                             |
| 8       | RPS      | Receive Stopped Enable.<br>The EMAC_DMA_IEN.RPS bit, when set with Abnormal Interrupt Summary Enable in this register, enables the Receive Stopped Interrupt is enabled. When this bit is reset, Receive Stopped Interrupt is disabled.                                                                                                                             |
| 7       | RU       | Receive Buffer Unavailable Enable.<br>The EMAC_DMA_IEN.RU bit, when set with Abnormal Interrupt Summary Enable in this register, enables the Receive Buffer Unavailable Interrupt. When this bit is reset, the Receive Buffer Unavailable Interrupt is disabled.                                                                                                    |

**Table 23-161:** EMAC\_DMA\_IEN Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                       |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6       | RI       | Receive Interrupt Enable.<br>The EMAC_DMA_IEN.RI bit, when set with Normal Interrupt Summary Enable in this register, enables the Receive Interrupt. When this bit is reset, Receive Interrupt is disabled.                                                   |
| 5       | UNF      | Underflow Interrupt Enable.<br>The EMAC_DMA_IEN.UNF bit, when set with Abnormal Interrupt Summary Enable in this register, enables the Transmit Underflow Interrupt. When this bit is reset, Underflow Interrupt is disabled.                                 |
| 4       | OVF      | Overflow Interrupt Enable.<br>The EMAC_DMA_IEN.OVF bit, when set with Abnormal Interrupt Summary Enable in this register, enables the Receive Overflow Interrupt. When this bit is reset, Overflow Interrupt is disabled.                                     |
| 3       | TJT      | Transmit Jabber Timeout Enable.<br>The EMAC_DMA_IEN.TJT bit, when set with Abnormal Interrupt Summary Enable in this register, enables the Transmit Jabber Timeout Interrupt. When this bit is reset, Transmit Jabber Timeout Interrupt is disabled.          |
| 2       | TU       | Transmit Buffer Unavailable Enable.<br>The EMAC_DMA_IEN.TU bit, when set with Normal Interrupt Summary Enable in this register, enables the Transmit Buffer Unavailable Interrupt. When this bit is reset, Transmit Buffer Unavailable Interrupt is disabled. |
| 1       | TPS      | Transmit Stopped Enable.<br>The EMAC_DMA_IEN.TPS bit, when set with Abnormal Interrupt Summary Enable in this register, enables the Transmission Stopped Interrupt. When this bit is reset, Transmission Stopped Interrupt is disabled.                       |
| 0       | TI       | Transmit Interrupt Enable.<br>The EMAC_DMA_IEN.TI bit, when set with Normal Interrupt Summary Enable in this register, enables the Transmit Interrupt. When this bit is reset, Transmit Interrupt is disabled.                                                |

## DMA Missed Frame Register

The EMAC\_DMA\_MISS\_FRM register contains counters for EMAC DMA missed frames and buffer overflows.

EMAC\_DMA\_MISS\_FRM: DMA Missed Frame Register - R/W

Reset = 0x0000 0000

Figure 23-137: EMAC\_DMA\_MISS\_FRM Register Diagram

Table 23-162: EMAC\_DMA\_MISS\_FRM Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                      |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 28      | OVFFIFO  | Overflow bit for FIFO Overflow Counter.<br>The EMAC_DMA_MISS_FRM.OVFFIFO bit holds the overflow bit for FIFO Overflow Counter.                                                               |
| 27:17   | MISSFROV | Missed Frames Buffer Overflow.<br>The EMAC_DMA_MISS_FRM.MISSFROV bits indicate the number of frames missed by the application due to buffer overflow.                                        |
| 16      | OVFMIS   | Overflow bit for Missed Frame Counter.<br>The EMAC_DMA_MISS_FRM.OVFMIS bit holds the overflow bit for the Missed Frame Counter.                                                              |
| 15:0    | MISSFRUN | Missed Frames Unavailable Buffer.<br>The EMAC_DMA_MISS_FRM.MISSFRUN bits indicate the number of frames missed by the controller because of the Application Receive Buffer being unavailable. |

DMA Rx Interrupt Watch Dog Register

The EMAC\_DMA\_RXIWDOG register contains the timeout value for the EMAC DMA receive interrupt watch dog timer.

EMAC\_DMA\_RXIWDOG: DMA Rx Interrupt Watch Dog Register - R/W

Reset = 0x0000 0000

Figure 23-138: EMAC\_DMA\_RXIWDOG Register Diagram

Table 23-163: EMAC\_DMA\_RXIWDOG Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0     | RIWT     | RI WatchDog Timer Count.<br>The EMAC_DMA_RXIWDOG.RIWT bit field indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the RxDMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watch-dog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when RI bit is set high because of automatic setting of RI as per RDES1[31] of any received frame. |

DMA SCB Bus Mode Register

The EMAC\_DMA\_BMMODE register selects EMAC DMA system cross bar bus mode features.

**EMAC\_DMA\_BMMODE: DMA SCB Bus Mode Register - R/W**

Reset = 0x0011 0001

**Figure 23-139: EMAC\_DMA\_BMMODE Register Diagram**

**Table 23-164: EMAC\_DMA\_BMMODE Register Fields**

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                        |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 22:20   | WROSRLMT | SCB Maximum Write Outstanding Request.<br>The EMAC_DMA_BMMODE.WROSRLMT bit field's value limits the maximum outstanding request on the SCB write interface. Maximum outstanding requests = WR_OSR_LMT+1. EMAC-SCB supports up to 4 outstanding write requests. |
| 18:16   | RDOSRLMT | SCB Maximum Read Outstanding Request.<br>The EMAC_DMA_BMMODE.RDOSRLMT bit field's value limits the maximum outstanding request on the SCB read interface. Maximum outstanding requests = RD_OSR_LMT+1. EMAC-SCB supports up to 4 outstanding read requests.    |
| 12      | AAL      | Address Aligned Beats.<br>The EMAC_DMA_BMMODE.AAL bit (read-only) reflects the AAL bit of DMA Bus mode register. When this bit is set to 1, EMAC-SCB performs address-aligned burst transfers on both read and write channels.                                 |
| 3       | BLEN16   | SCB Burst Length 16.<br>The EMAC_DMA_BMMODE.BLEN16 bit, when set (or when UNDEF is set to 1), directs the EMAC-SCB to select a burst length of 16 on the SCB master interface.                                                                                 |

Table 23-164: EMAC\_DMA\_BMMODE Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2       | BLN8     | SCB Burst Length 8.<br>The EMAC_DMA_BMMODE.BLN8 bit, when set (or when UNDEF is set to 1), directs the EMAC-SCB to select a burst length of 8 on the SCB master interface.                                                                                                                                                                                                                                                                                |
| 1       | BLN4     | SCB Burst Length 4.<br>The EMAC_DMA_BMMODE.BLN4 bit, when set (or when UNDEF is set to 1), directs the EMAC-SCB to select a burst length of 4 on the SCB master interface.                                                                                                                                                                                                                                                                                |
| 0       | UNDEF    | SCB Undefined Burst Length.<br>The EMAC_DMA_BMMODE.UNDEF bit (read-only) indicates the complement (invert) value of FB bit in DMA Bus Mode Register. When this bit is set to 1, the EMAC-SCB is allowed to perform any burst length equal to or below the maximum allowed burst length as programmed in bits[3:1]. When this bit is set to 0, the EMAC-SCB is allowed to perform only fixed burst lengths as indicated by 16/8/4, or a burst length of 1. |

DMA SCB Status Register

The EMAC\_DMA\_BMSTAT register indicates EMAC DMA system cross bar status.

EMAC\_DMA\_BMSTAT: DMA SCB Status Register - R/W

Reset = 0x0000 0000

Figure 23-140: EMAC\_DMA\_BMSTAT Register Diagram

**Table 23-165:** EMAC\_DMA\_BMSTAT Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1       | BUSRD    | Bus (SCB master) Read Active.<br>The EMAC_DMA_BMSTAT.BUSRD bit, when high, indicates that SCB Master's read channel is active and transferring data.   |
| 0       | BUSWR    | Bus (SCB master) Write Active.<br>The EMAC_DMA_BMSTAT.BUSWR bit, when high, indicates that SCB Master's write channel is active and transferring data. |

## DMA Tx Descriptor Current Register

The EMAC\_DMA\_TXDSC\_CUR register contains the current DMA transmit descriptor.

**EMAC\_DMA\_TXDSC\_CUR: DMA Tx Descriptor Current Register - R/W**

Reset = 0x0000 0000

**Figure 23-141:** EMAC\_DMA\_TXDSC\_CUR Register Diagram

**Table 23-166:** EMAC\_DMA\_TXDSC\_CUR Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                               |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | ADDR     | Host Transmit Descriptor Address.<br>The EMAC_DMA_TXDSC_CUR.ADDR bit field points to the start address of the current Transmit Descriptor read by the DMA. Pointer updated by DMA during operation. Cleared on Reset. |

## DMA Rx Descriptor Current Register

The EMAC\_DMA\_RXDSC\_CUR register contains the current DMA receive descriptor.

EMAC\_DMA\_RXDSC\_CUR: DMA Rx Descriptor Current Register - R/W

Reset = 0x0000 0000

Figure 23-142: EMAC\_DMA\_RXDSC\_CUR Register Diagram

Table 23-167: EMAC\_DMA\_RXDSC\_CUR Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                     |
|---------|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | ADDR     | Host Receive Current Descriptor Address.<br>The EMAC_DMA_RXDSC_CUR.ADDR bit field points to the start address of the current Receive Descriptor read by the DMA. Pointer updated by DMA during operation. Cleared on Reset. |

DMA Tx Buffer Current Register

The EMAC\_DMA\_TXBUF\_CUR register holds the pointer to the current transmit DMA buffer.

EMAC\_DMA\_TXBUF\_CUR: DMA Tx Buffer Current Register - R/W

Reset = 0x0000 0000

Figure 23-143: EMAC\_DMA\_TXBUF\_CUR Register Diagram

Table 23-168: EMAC\_DMA\_TXBUF\_CUR Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                        |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | ADDR     | Host Transmit Current Buffer Address.<br>The EMAC_DMA_TXBUF_CUR.ADDR bit field points to the current Transmit Buffer Address being read by the DMA. Pointer updated by DMA during operation. Cleared on Reset. |

DMA Rx Buffer Current Register

The EMAC\_DMA\_RXBUF\_CUR register holds the pointer to the current receive DMA buffer.

EMAC\_DMA\_RXBUF\_CUR: DMA Rx Buffer Current Register - R/W

Reset = 0x0000 0000

Figure 23-144: EMAC\_DMA\_RXBUF\_CUR Register Diagram

Table 23-169: EMAC\_DMA\_RXBUF\_CUR Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                      |
|---------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0    | ADDR     | Host Receive Current Buffer Address.<br>The EMAC_DMA_RXBUF_CUR.ADDR bit field points to the current Receive Buffer address being read by the DMA. Pointer updated by DMA during operation. Cleared on Reset. |

## 24 Removable Storage Interface (RSI)

The removable storage interface (RSI) controller is a fast, synchronous peripheral that uses various protocols to communicate with MMC, SD, and SDIO cards as well as CE-ATA hard drives. The RSI is compatible with the following protocols.

- MMC (Multimedia Card) bus protocol
- SD (Secure Digital) bus protocol
- SDIO (Secure Digital Input Output) bus protocol
- CE-ATA (Consumer Electronic ATA)

All of these storage solutions use similar interface protocols. The main difference between MMC and SD support is the initialization sequence. The main difference between SD and SDIO support is the use of interrupt and read wait signals for SDIO. CE-ATA devices require handling of larger block sizes of 4K bytes and implement a device interrupt scheme known as the command completion signal (CCS).

**NOTE:** The RSI does not support the SPI bus protocol

### RSI Features

RSI includes the following features:

- Support for a single SD or SDIO card
- Support for a single MMC device (removable or embedded)
- Support for 1- and 4-bit SD modes (SPI mode is not supported)
- Support for 1-, 4-, and 8-bit MMC modes (SPI mode is not supported)
- Support for 4- and 8-bit CE-ATA devices
- Programmable clock frequency generated from SCLK
- Card detection capabilities
- SDIO interrupt and read wait features
- Command completion signal recognition and disable for CE-ATA device support
- High-capacity card support such as SDHC implemented within software
- 512-bit transmit/receive FIFO

- DMA channel with 32-bit DMA access bus

**Table 24-1:** RSI Specifications

| Feature                  | Availability |
|--------------------------|--------------|
| <b>Protocol</b>          |              |
| Master-Capable           | Yes          |
| Slave-Capable            | No           |
| Transmission Simplex     | Yes          |
| Transmission Half-Duplex | Yes          |
| Transmission Full-Duplex | No           |
| <b>Access Type</b>       |              |
| Data Buffer              | Yes          |
| Core Data Access         | Yes          |
| DMA Data Access          | Yes          |
| DMA Channels             | 1            |
| DMA Descriptor           | Yes          |
| Boot Capable             | Yes          |
| Local Memory             | No           |
| Clock Operation          | SCLK0/2      |

## RSI Functional Description

The following sections provide details on the RSI functionality.

## RSI Register List

**Table 24-2:** RSI Module Registers

| Name              | Description                               |
|-------------------|-------------------------------------------|
| RSI_CTL           | Control Register                          |
| RSI_ARG           | Argument Register                         |
| RSI_CMD           | Command Register                          |
| RSI_RESP_CMD      | Response Command Register                 |
| RSI_RESP0         | Response 0 Register                       |
| RSI_RESP1         | Response 1 Register                       |
| RSI_RESP2         | Response 2 Register                       |
| RSI_RESP3         | Response 3 Register                       |
| RSI_DATA_TMR      | Data Timer Register                       |
| RSI_DATA_LEN      | Data Length Register                      |
| RSI_DATA_CTL      | Data Control Register                     |
| RSI_DATA_CNT      | Data Count Register                       |
| RSI_XFRSTAT       | Status Register                           |
| RSI_XFRSTAT_CLR   | Status Clear Register                     |
| RSI_XFR_IMSK0     | Interrupt 0 Mask Register                 |
| RSI_XFR_IMSK1     | Interrupt 1 Mask Register                 |
| RSI_FIFO_CNT      | FIFO Counter Register                     |
| RSI_CEATA         | This register contains bit to dis CCS gen |
| RSI_BOOT_TCNTR    | Boot Timing Counter Register              |
| RSI_BACK_TOUT     | Boot Acknowledge Timeout Register         |
| RSI_SLP_WKUP_TOUT | Sleep Wakeup Timeout Register             |
| RSI_BLKSZ         | Block Size Register                       |

**Table 24-2:** RSI Module Registers (Continued)

| Name        | Description                        |
|-------------|------------------------------------|
| RSI_FIFO    | Data FIFO Register                 |
| RSI_STAT0   | Exception Status Register          |
| RSI_IMSK0   | Exception Mask Register            |
| RSI_CFG     | Configuration Register             |
| RSI_RD_WAIT | Read Wait Enable Register          |
| RSI_PID0    | Peripheral Identification Register |
| RSI_PID1    | Peripheral Identification Register |
| RSI_PID2    | Peripheral Identification Register |
| RSI_PID3    | Peripheral Identification Register |

## ADSP-BF60x RSI Interrupt List

**Table 24-3:** ADSP-BF60x RSI Interrupt List

| Description      | ID | DMA Channel | Sensitivity |
|------------------|----|-------------|-------------|
| RSI0 DMA Channel | 61 | 10          | LEVEL       |
| RSI0 Interrupt 0 | 62 |             | LEVEL       |
| RSI0 Interrupt 1 | 63 |             | LEVEL       |

## ADSP-BF60x RSI Trigger List

**Table 24-4:** Masters ADSP-BF60x RSI Trigger List

| Description      | ID | Sensitivity |
|------------------|----|-------------|
| RSI0 DMA Channel | 30 | PULSE/EDGE  |
|                  |    |             |

**Table 24-5:** Slaves ADSP-BF60x RSI Trigger List

| Description      | ID | Sensitivity |
|------------------|----|-------------|
| RSI0 DMA Channel | 30 |             |
|                  |    |             |

## RSI Clock Configuration

The RSI is a fast, synchronous peripheral with a programmable clock frequency that is supplied by the *RSI\_CLK* signal. The interface between the RSI and the internal buses operates at *SCLKx* frequency. Communication between the clock domain that is supplied externally from the RSI on the *RSI\_CLK* signal and the RSI access to the internal busses is accomplished using synchronizers in the RSI module. The *RSI\_CLK* frequency is configured by the 8-bit *CLKDIV* field and the *BYPASS* bit of the *RSI\_CTL* register.

If *BYPASS* is set, the clock frequency driven on the *RSI\_CLK* signal is derived directly from *SCLKx*. If *BYPASS* is cleared, the clock divider logic provides an *RSI\_CLK* frequency as shown below, where *CLKDIV* is an 8-bit value ranging between 0 and 255

$$RSI\_CLK = SCLKx / 2^{(CLKDIV+1)}$$

The *RSI\_CLK* output is enabled or disabled by the *CLKEN* bit in the *RSI\_CTL* register and a power save feature is implemented by setting *PWRSAVE*, which disables the *RSI\_CLK* output when there are no transfers taking place on the RSI interface.

## RSI Interface Configuration

The RSI supports multiple card types under various protocols. Different card types may require slightly different interface configurations.

The command signal on MMC cards operates in two different modes depending upon the operating mode of the card. During the card identification mode, the command signal operates in open-drain configuration; but when the card enters data transfer mode, the signal is configured to push-pull mode.

**NOTE:** The internal pull-up resistor of the *RSI\_CMD* signal is only intended to keep the signal from floating. The internal pull-up resistor is not sufficient during the card identification phase when the MMC card *RSI\_CMD* signal is operating in open-drain mode. If support for MMC devices is required, an external pull-up resistor should be added to the *RSI\_CMD* signal as detailed in the JEDEC standard.

The bus width used for the data transfers is configurable to 1-bit, 4-bits, or 8-bits using the `BUSWID` field in the `RSI_CTL` register.

To stop signals from floating when no card is inserted or during times when all card drivers are in a high-impedance mode, various pull-up and pull-down resistor configurations can be enabled on the `RSI_DATAx` signals. The `RSI_CFG` register provides the following options.

- Enable or disable a pull-up resistor on the `RSI_DATA3` signal
- Enable or disable pull-up resistors on the `RSI_DATA7` through `RSI_DATA4` and `RSI_DATA2` through `RSI_DATA0` signals.

## Card Detection

The RSI allows for software to detect when a card is inserted into its slot. There are a number of ways that this card detection can be performed.

**Figure 24-1:** RSI Socket Interface

1. Using RSI\_DATA3 – SD and SDIO cards use an internal pull-up resistor on the RSI\_DATA3 line as a card detect signal to indicate to the host that a card is present. In order to use the RSI\_DATA3 signal for card detection, an external pull down resistor should be added to the pin to pull the pin low during the time a card is not inserted. When a card is inserted into the slot, a rising edge is detected on RSI\_DATA3 by the RSI and **SDCARD** bit in the **RSI\_STAT0** register is set. Once the card has been correctly identified, the **SDCARD** interrupt should be cleared and disabled. The pull-up resistor in the SD card should be disabled by issuing the **SET\_CLR\_CARD\_DETECT** command. When using the RSI\_DATA3 signal for card detection with an external pull-down resistor, do not enable the internal pull-up resistor by setting **DAT3PUP** in **RSI\_CFG** register.
2. Using SD/MMC Socket and GPIO Interrupt - The recommended method of detecting the insertion of a card is to use the card detect feature that is made available through most sockets. Sockets supporting this feature can have the card detect pin de-bounced and connected to a GPIO pin in order to allow not only interrupt driven card detection but also interrupt driven card removal. This is the most reliable

and efficient method of detecting the insertion and removal of a card as some MMC devices may not implement the card detect pull-up resistor on the *RSI\_DATA3* signal. Once a card is detected, the GPIO pin can have the interrupt level inverted to then generate an interrupt on card removal.

3. Using Software Polling – The final approach to detecting the insertion and removal of a card is to simply use software polling. Software would poll the slot periodically using the card identification commands for the supported card types. Once a card is inserted, this will result in valid responses being sent back to the host; when the card is removed, command and data timeout errors will be observed.

## RSI Power Saving Configuration

The RSI requires two internal clock signals that are derived directly from SCLKx. One of these clock signals is routed to the clock divider and generates the RSI\_CLK clock.

These clocks must be enabled by setting *CLKSEN* in the *RSI\_CFG* register for the RSI to function. Clearing *CLKSEN* disables the RSI regardless of other RSI clock configurations. The RSI\_CLK signal can be enabled or disabled using *CLKEN* in the *RSI\_CTL* register.

Additional power saving options can be implemented by setting *PWRSAVE* in the *RSI\_CTL* register which disables the RSI\_CLK output when there are no transfers taking place on the RSI interface. These configurations are shown in the table "RSI Power Saving Configurations".

**Table 24-6:** RSI Power Saving Configurations

| CLKSEN(RSI_CFG) | CLKEN(RSI_CTL) | PWRSAVE(RSI_CTL) | RSI State | RSI_CLK Output                                  |
|-----------------|----------------|------------------|-----------|-------------------------------------------------|
| 0               | 0              | 0                | Disabled  | No clock                                        |
| 0               | 0              | 1                | Disabled  | No clock                                        |
| 0               | 1              | 0                | Disabled  | No clock                                        |
| 0               | 1              | 1                | Disabled  | No clock                                        |
| 1               | 0              | 0                | Enabled   | No clock                                        |
| 1               | 0              | 1                | Enabled   | No clock                                        |
| 1               | 1              | 0                | Enabled   | Continuous clock <sup>1</sup>                   |
| 1               | 1              | 1                | Enabled   | Clock only driven during transfers <sup>1</sup> |

<sup>1</sup> The *PWRON* field of the *RSI\_CFG* register must be set to 0x3. If *PWRON* is cleared, the clock will not output.

## RSI Command-Response Interface

The RSI sends commands to and receives responses from the card using the RSI\_CMD signal. The command to be sent to the card is issued by writing to the RSI\_CMD register. This register contains a 6-bit `IDX` field that contains the command index to be sent to the card. The command index provides support for a total of 64 commands—0 (CMD0) to 63 (CMD63). Some commands require an argument to be sent along with the command, such as an address for a read transaction. An argument is always sent with the command and it is the responsibility of the card to either ignore or use the argument field based on the command that is received. The argument sent with the command is provided using the RSI\_ARG register.

All command transfers are protected by a 7-bit cyclic redundancy check (CRC) code, more commonly referred to as a CRC7 checksum. This allows for transmission errors to be detected and for the command to be re-issued to the card in the event of an error. All commands sent to the card are composed of 48-bits as shown in the table below.

**Table 24-7:** RSI Command Format

| Bit Position | Width | Value | Description     |
|--------------|-------|-------|-----------------|
| 47           | 1     | 0     | Start bit       |
| 46           | 1     | 1     | Transmitter bit |
| [45:40]      | 6     | -     | Command index   |
| [39:8]       | 32    | -     | Argument        |
| [7:1]        | 7     | -     | CRC7 checksum   |
| 0            | 1     | 1     | End bit         |

The RSI\_CMD register also provides configuration information about whether a response is to be expected back from the card and the type of response.

The RSI can be configured using the `RSP` and `LRSP` fields of the RSI\_CMD register to expect the following response types.

- No response
- Short response (see the table "RSI Short Response Format")
- Long response (see the table "RSI Long Response Format")

**Table 24-8:** RSI Short Response Format

| Bit Position | Width | Value | Description |
|--------------|-------|-------|-------------|
| 47           | 1     | 0     | Start bit   |

**Table 24-8:** RSI Short Response Format (Continued)

| Bit Position | Width | Value | Description                                      |
|--------------|-------|-------|--------------------------------------------------|
| 46           | 1     | 0     | Transmitter bit                                  |
| [45:40]      | 6     | -     | Command index or check bits <sup>1</sup>         |
| [39:8]       | 32    | -     | Card status, register contents or argument field |
| [7:1]        | 7     | -     | CRC7 checksum or check bits <sup>2</sup>         |
| 0            | 1     | 1     | End bit                                          |

1 Responses that do not contain the command index have b#111111 in the check bits field.

2 Responses that do not contain a CRC7 check sum have b#111111 in the check bits field.

**Table 24-9:** RSI Long Response Format

| Bit Position | Width | Value  | Description                                            |
|--------------|-------|--------|--------------------------------------------------------|
| 135          | 1     | 0      | Start bit                                              |
| 134          | 1     | 0      | Transmitter bit                                        |
| 133:128      | 6     | 111111 | Check bits <sup>1</sup>                                |
| 127:1        | 127   | -      | Register contents including internal CRC7 <sup>2</sup> |
| 0            | 1     | 1      | End bit                                                |

1 Responses that do not contain the command index have b#111111 in the check bits field.

2 Responses that do not contain a CRC7 check sum have b#111111 in the check bits field.

Like the commands, all responses are sent on the RSI\_CMD signal. A response always has a 0 start bit followed by a 0 transmission bit to indicate the transfer is from card to the RSI. Unlike the commands issued by the RSI, not all responses are protected by a CRC7 checksum. Refer to the appropriate specification for full details on the response formats for a specific device and whether they are protected by a CRC7 checksum.

When a short response is received, the response is broken down by the RSI. The 32-bit field containing bits[39:8] is stored to RSI\_RESP0, where bit 39 of the response corresponds to bit 31 of RSI\_RESP0 and bit 8 of the response to bit 0 of RSI\_RESP0. Bits[45:40] of the response are stored to the RESP\_CMD field of the RSI\_RESP\_CMD register.

For a long response, bits [127:1] of the response are stored in RSI\_RESP3–0. Bit 31 of RSI\_RESP0 contains the most significant bit (bit 127) of the response and bit 0 of RSI\_RESP3 contains bit 1 of the response. Bit 31 of RSI\_RESP3 is always zero.

The following figure shows the command path state machine. For the state machine to be active, the RSI must be enabled through CLKEN bit of the RSI\_CTL register. Disabling the clocks to the RSI results in the state machine returning to the IDLE state.

**Figure 24-2:** RSI Command Path State Machine

The command path state machine is responsible for setting and clearing a number of status flags in the RSI\_XFRSTAT register. The following table lists the status flags and exception flags that are affected by the command path state machine.

**Table 24-10:** RSI Command Path Status Flags

| RSI_XFRSTAT/RSI_STAT Flag | Description                     | State Flag Set in |
|---------------------------|---------------------------------|-------------------|
| CMDACT                    | Command transfer is in progress | WAIT_S            |

Table 24-10: RSI Command Path Status Flags (Continued)

| RSI_XFRSTAT/RSI_STAT Flag | Description                                                                        | State Flag Set in |
|---------------------------|------------------------------------------------------------------------------------|-------------------|
| CMDSENT                   | Command without response sent successfully                                         | SEND              |
| CMDTO                     | Response timeout occurred (64 RSI_CLK cycles)                                      | WAIT_S            |
| CMDCRCFAIL                | Response CRC failure                                                               | RECEIVE           |
| RSPEND                    | Response received successfully (and CRC check passed if the CRCDIS bit is cleared) | RECEIVE           |
| CEATAINT                  | CE-ATA command completion signal detected                                          | CEATA_INT_WAIT    |

The command path operates in a half-duplex mode, so that commands and responses can either be sent or received. If the state machine is not in the SEND state, the RSI\_CMD output is in high impedance state.

The following figure describes a typical command and response transfer, the RSI\_CMD signal is sampled by the card and the host on the rising edge of RSI\_CLK.

Figure 24-3: RSI Command Transfer

The following sections describes the RSI command path states.

## IDLE State

The command path state machine remains in the IDLE state when it is not active. The command path state machine is enabled and leaves the IDLE state when the EN bit in the RSI\_CMD register is set. The state goes to the PEND state if the PNDEN bit in the RSI\_CMD is set; otherwise it enters the SEND state.

When the command path state machine returns to the IDLE state from another state and the return is not due to RSI being disabled or reset—the state machine remains in the IDLE state for at least eight RSI\_CLK cycles. During this time, the RSI will continue to drive the RSI\_CLK signal even if the PWRSAVE feature is enabled. This allows the card to complete the current operation. If enabled again, the state machine leaves the IDLE state only after the eight RSI\_CLK cycles have passed.

## PEND State

The RSI enters the PEND state if the `PNDEN` bit in the `RSI_CMD` register is set. The state machine remains in the PEND state until it is notified by the data path sub block that a data transfer has completed. This is indicated by the `DATEND` flag being set when `RSI_DATA_CNT` decrements to zero. This mode allows for the automatic transmission of a `STOP_TRANSMISSION` command after reading or writing the required amount of data for stream-based transactions.

The `PNDEN` feature is not functional for block-based transfers and cannot be used to automatically issue the `STOP_TRANSMISSION` command for `MULTIPLE_BLOCK_READ` or `MULTIPLE_BLOCK_WRITE` operations.

## SEND State

During the SEND state, the RSI sets the `CMDACT` flag in the `CMD_XFRSTAT` register to indicate a transfer is in progress. The behavior of the state machine after the command is sent, depends upon whether the command expects a response back from the card.

If no response is expected, the RSI clears the `CMDACT` flag and sets the `CMDSENT` flag to indicate that a command operation without a response has been completed. The state then goes to IDLE.

If a response is expected, the RSI enters the WAIT state.

## WAIT State

In the WAIT state, the RSI waits for a response to be received on the RSI\_CMD signal. Upon entering this state, an internal timer starts. If the response is not received within 64 RSI\_CLK cycles, the `CMDTO` flag is set and the `CMDACT` flag is cleared. The state machine then enters the IDLE state, awaiting the next action.

A response, sent back from the card and indicated by the 0 start bit on the RSI\_CMD signal, transitions the RSI to the RECEIVE state to receive a 48- or 136-bit response.

The WAIT state can also detect card interrupts. This is an optional feature that applies only to MMC cards. This feature is enabled by setting the `IEN` bit within `RSI_CMD`. When `IEN` is set, the timeout timer that is normally started upon entry to the WAIT state is disabled. The RSI remains in this state until a card interrupt is detected. Cards that implement this feature may have functions with a delayed response that is triggered by an internal event in the card. Once the event is triggered the card sends the response. The RSI then detects this start bit of the response and proceeds to the RECEIVE state.

## RECEIVE State

In the RECEIVE state the RSI reads the response on the RSI\_CMD signal from the card. Upon receiving either the short or long response, if the response passes the CRC check, the CMDACT flag is cleared and the RESPEND flag is set. If the CRC check fails, the CMDCRCFAIL flag is set. In either case, the state machine then goes to the IDLE state.

Some CE-ATA commands require additional functionality in this state. A command completion signal must be sent back to the host upon completion of a specific task. For commands that require this functionality, the CEATAMODE and CEATAIEN bits of the RSI\_DATA\_CTL register should be set prior to enabling the command path state machine. After receiving the response, the state machine then enters the CEATA\_INT\_WAIT state.

## CEATA\_INT\_WAIT State

In this state, the RSI waits for the CE-ATA device to issue the command completion signal. This is indicated by the device sending a “0” on the RSI\_CMD signal. Upon detection of the command completion signal, the CMDACT flag is cleared and the CEATAINT flag of the RSI\_STAT0 register is set. Alternatively, the command completion signal of the CE-ATA device can be disabled by the RSI. This is performed by setting the INT\_DIS bit of the RSI\_CEATA register, at which point the state machine enters the CEATA\_INT\_DIS state. The INT\_DIS bit can be set prior to enabling the command path state machine. The CCSD sequence is issued after the response is received rather than having to wait for the response before setting INT\_DIS.

## CEATA\_INT\_DIS State

In this state, the RSI issues the command completion signal disable sequence on the RSI\_CMD signal before it transitions to the IDLE state and clears the CMDACT flag. The command completion signal disable sequence issued is the binary sequence b#00001.

## RSI Command Path CRC

The command CRC generator of the RSI calculates the 7-bit CRC check-sum for all 40 bits preceding the CRC code for both 48-bit commands and 48-bit responses. This includes the start bit, transmitter bit, command index, and command argument (or card status). The 7-bit CRC checksum is calculated for the first 120 bits of the register contents field for the long response format. Note that the start bit, transmitter bit, and the six check bits are not used in the CRC calculation for the long response. The command and response CRC checksum is a 7-bit value that is calculated as follows:

$$\text{CRC}[6:0] = \text{Remainder } \frac{x_7 \times M(x)}{G(x)}$$

With:  $G(x) = x_7 + x_3 + 1$

and for a short response:

$$M(x) = x_{39} \cdot (\text{start bit}) + \dots + x_0 \cdot (\text{last bit before CRC})$$

or for a short response:

$$M(x) = x_{19} \cdot (\text{start bit}) + \dots + x_0 \cdot (\text{last bit before CRC})$$

## RSI Data Interface

Data transfers both to and from the RSI take place over the RSI data bus signals *RSI\_DATA7—0*. The RSI data bus width is configured by the *BUSWID* field of the *RSI\_CTL* register. The default is 1-bit bus mode, where the data is transferred over the *RSI\_DATA0* signal. 4-bit mode or 8-bit mode can be enabled after configuring the card for 4-bit or 8-bit mode of operation, respectively.

The RSI data path state machine operates at *RSI\_CLK* frequency. The state machine leaves the *IDLE* state when the *DATEN* field of the *RSI\_DATA\_CTL* register is set, enabling the data transfer. The state entered upon leaving the *IDLE* state is determined by *DATDIR*. The data path state machine is shown in the following figure.

**Figure 24-4:** RSI Data Path State Machine

The data path status flags are shown in the following table.

**Table 24-11:** RSI\_STATUS Flags

| RSI_XFRSTAT Flag | Description                                                                                                                                          | Status Flag Set in                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| TXACT            | Data transmit in progress                                                                                                                            | WAIT_S                                                                                                |
| RXACT            | Data receive in progress                                                                                                                             | WAIT_R                                                                                                |

| TXFIFOSTAT       | Transmit FIFO is half empty                                                                                                                          | SEND                                                                                                  |
| TXFIFOFULL       | Transmit FIFO is full                                                                                                                                | SEND                                                                                                  |
| TXFIFOZERO       | Transmit FIFO is empty                                                                                                                               | SEND                                                                                                  |
| TXUNDR           | Transmit FIFO under run error                                                                                                                        | SEND                                                                                                  |
| TXFIFORDY        | Valid data available in the transmit FIFO                                                                                                            | SEND                                                                                                  |
| RXFIFOSTAT       | Receive FIFO is half empty                                                                                                                           | RECEIVE                                                                                               |
| RXFIFOFULL       | Receive FIFO is full                                                                                                                                 | RECEIVE                                                                                               |
| RXFIFOZERO       | Receive FIFO is empty                                                                                                                                | RECEIVE                                                                                               |
| RXOVER           | Receive FIFO over run error                                                                                                                          | RECEIVE                                                                                               |

**Table 24-11:** RSI\_STATUS Flags (Continued)

| RSI_XFRSTAT Flag | Description                                 | Status Flag Set in |
|------------------|---------------------------------------------|--------------------|
| RXFIFORDY        | Valid data is available in the receive FIFO | RECEIVE            |

## RSI Data Transmit Path

The transmit path consists of the *WAIT\_S*, *SEND*, and *BUSY* states. *RSI\_BLK SZ*, *RSI\_DATA\_LEN* and *RSI\_DATA\_TMR* must be configured before enabling the data path state machine with *RSI\_DATA\_CTL*. Upon leaving the *IDLE* state and entering the *WAIT\_S* state, the RSI sets the *TXACT* flag and copies *RSI\_DATA\_LEN* into *RSI\_DATA\_CNT*.

The behavior of the *SEND* state depends on which transfer mode is configured.

- Stream Transfer Mode** - If the RSI is configured for stream transfer mode, it sends data to the card until *RSI\_DATA\_CNT* expires, at which point the *DATEND* flag is set and the state machine returns to the *IDLE* state. Additionally the transition of *RSI\_DATA\_CNT* to zero activates the command path state machine if it is currently in the *PEND* state. If at any point during the stream transfer the transmit FIFO becomes empty and data is not available in the FIFO by the time the next transfer is due to take place, the *TXUNDR* flag is set before returning to the *IDLE* state.
- Block Transfer Mode** - In block transfer mode, *RSI\_BLK SZ* bytes, as specified during the write to *RSI\_DATA\_CTL*, are transmitted. Each byte transferred also decrements *RSI\_DATA\_CNT*. Upon completion of the block transfer, the RSI appends an internally generated 16-bit CRC code and an end bit to the data transferred over the *RSI\_DATAx* signals. The RSI then waits for the card token response on the *RSI\_DATA0* line to indicate whether the data was received correctly by the card or not. If the CRC response token sent by the card indicates the data was received correctly, the *DATBLKEND* flag is set before moving to the *BUSY* state. If the data was not received correctly, the *DATCRCFAIL* flag is set before returning to the *IDLE* state. The decrementing of *RSI\_DATA\_CNT* to zero results in the *DATEND* flag being set. If the total number of bytes transmitted for the current block results in the *RSI\_DATA\_CNT* decrementing to zero and the number of bytes transferred is not equal to *RSI\_BLK SZ*, the transmission stops and the *DATCRCFAIL* flag is set. The data path returns to the *IDLE* state. If at any point during the block transfer the transmit FIFO becomes empty and data is not available in the FIFO by the time the next transfer is due to take place, the *TXUNDR* flag is set before returning to the *IDLE* state.

During the *BUSY* state, the RSI continuously samples *RSI\_DATA0* which at this point is driven low by the card to indicate that the card is busy. When a logic high state is detected, indicating that the card is no longer busy, the state machine returns to the *WAIT\_S* state. It then either returns to *IDLE* if all data has been sent or moves back to the *SEND* state to start another block transfer.

Upon entry to the *BUSY* state, the RSI started decrementing the timeout value specified by *RSI\_DATA\_TMR*. If the RSI timeout counter expires before the *RSI\_DATA0* signal is detected high, the RSI sets the *DATTO* flag and returns to the *IDLE* state.

## RSI Data Receive Path

The receive path consists of the *WAIT\_R* and the *RECEIVE* states. *RSI\_BLKSZ*, *RSI\_DATA\_LEN* and *RSI\_DATA\_TMR* must be configured, before enabling the data path state machine with *RSI\_DATA\_CTL*. Upon leaving the *IDLE* state and entering the *WAIT\_R* state, the RSI sets the *RXACT* flag and copies *RSI\_DATA\_LEN* into *RSI\_DATA\_CNT*. The behavior of the *RECEIVE* state is influenced by the transfer mode.

Once the receive path has entered the *WAIT\_R* state after being enabled for a receive transaction, the RSI starts decrementing the timeout value supplied by the *RSI\_DATA\_TMR*.

If the RSI is configured for a 1-bit data bus, the *DATTO* flag is set if a start bit is not detected on the *RSI\_DATA0* signal before the timeout counter reaches zero. The state machine then returns to the *IDLE* state.

If the RSI is configured for 4-bit bus mode and the start bit is not detected on all four *RSI\_DATAx* signals before the timeout counter expires—the *DATTO* flag is set. The state machine returns to the *IDLE* state. If a start bit is detected on some, but not all, of the *RSI\_DATAx* signals on the same sampled clock cycle, then the *SBITERR* flag is set and the state machine returns to the *IDLE* state. Upon correct detection of the start bit, the state machine moves into the *RECEIVE* state.

The behavior of the *RECEIVE* state differs for stream and block transfers.

- **Stream Transfer Mode** - For stream transfers, received data is packed into bytes and written to the data FIFO. Data is continuously received and written to the data FIFO until *RSI\_DATA\_CNT* decrements to zero. When the counter reaches zero, the remaining data in the shift register is written into the FIFO, the *DATEND* flag is set and the state machine transitions to the *WAIT\_R* state. When the receive FIFO is detected empty, the *RXFIFOZERO* flag is set and the state goes to the *IDLE* state. If the data FIFO becomes full and data has not been read from the FIFO prior to the next byte being written to the FIFO, then the *RXOVER* flag is set. The state goes to the *WAIT\_R* state then into the *IDLE* state.
- **Block Transfer Mode** - In block transfer mode, the received data is packed into bytes and written to the data FIFO. When *RSI\_BLKSZ* bytes have been received, the RSI reads the 16-bit CRC check bits. If the received CRC matches the internally calculated CRC, the *DATBLKEND* flag is set and the state transitions to the *WAIT\_R* state. If the *RSI\_DATA\_CNT* counter expires in alignment with the end of a *RSI\_BLKSZ* block, the *DATEND* and *DATBLKEND* flags are set, and the state goes to the *WAIT\_R* state. When the receive FIFO is detected empty, the *RXFIFOZERO* flag is set and the state goes to the *IDLE* state. If *RSI\_DATA\_CNT* expires before the end of a *RSI\_BLKSZ* block, the *DATCRCFAIL* flag is set. The state goes to the *IDLE* state.

## RSI Data Path CRC

The data CRC generator of the RSI calculates the 16-bit CRC checksum for all bits sent or received for a given block transaction. The data path CRC generator is not enabled for stream based data transfers. For a 1-bit bus configuration, the 16-bit CRC is calculated for all data sent on the *RSI\_DATA0* signal. For a 4-bit-wide data bus, the 16-bit CRC is calculated separately for each *RSI\_DATAx* signal. The data path CRC checksum is a 16-bit value calculated as follows.

$$\text{CRC}[15:0] = \text{Remainder} \frac{x_{16} \cdot M(x)}{G(x)}$$

with:

$$G(x) = x_{16} + x_{12} + x_5 + 1$$

where:

$$M(x) = x_{((8 \times \text{DTX\_BLK\_LGTH}) - 1)} \cdot (\text{first data bit}) + \dots + x_0 \cdot (\text{last data bit})$$

## RSI Data FIFO

The data FIFO is a 32-bit wide, 16-word deep data buffer with transmit and receive logic. The FIFO is configuration depends on the state of the `TXACT` and `RXACT` flags. If `TXACT` is set, the FIFO operates as a transmit FIFO supplying data to the RSI for transfer to the card. If `RXACT` flag is set, the FIFO operates as a receive FIFO, where the RSI writes data received from the card. If neither `TXACT` nor `RXACT` flags are set, then the FIFO is disabled.

When the transmit FIFO is disabled, all the transmit status flags are de-asserted and the transmit read and write pointers are reset. The RSI asserts the `TXACT` flag upon starting a data transfer. During the data transfer the transmit logic maintains the transmit FIFO status flags shown in the following table.

**Table 24-12:** RSI Transmit FIFO Status Flags

| RSI_XFRSTAT Flag | Description                               |
|------------------|-------------------------------------------|
| TXFIFOSTAT       | Transmit FIFO is half empty               |
| TXFIFOFULL       | Transmit FIFO is full                     |
| TXFIFOZERO       | Transmit FIFO is empty                    |
| TXUNDER          | Transmit FIFO under run error             |
| TXFIFORDY        | Valid data available in the transmit FIFO |

When the receive FIFO is disabled, all receive status flags are de-asserted and the receive read and write pointers are reset. The RSI asserts the `RXACT` flag upon starting a data read transaction. During the data transfer, the receive logic maintains the receive FIFO status flags shown in Table "RSI Receive FIFO Status Flags" .

**Table 24-13:** RSI Receive FIFO Status Flags

| RSI_XFRSTAT Flag | Description                              |
|------------------|------------------------------------------|
| RXFIFOSTAT       | Receive FIFO is half empty               |
| RXFIFOFULL       | Receive FIFO is full                     |
| RXFIFOZERO       | Receive FIFO is empty                    |
| RXOVER           | Receive FIFO over run error              |
| RXFIFORDY        | Valid data available in the receive FIFO |

## Card Busy/Ready Detection

Some commands, like CMD6, may assert the busy signal by driving RSI\_DAT0 line low, two cycles after the end bit of the command. RSI\_DAT1-7 lines are driven by the card though their values are not relevant. Software should program the CHKBUSY bit of RSI\_CMD register to enable this busy checking. If this bit is enabled for a particular command, third cycle from the end bit of the command is checked for RSI\_DAT0 going low. If RSI\_DAT0 goes low at this cycle, BUSYMODE bit of RSI\_STAT0 register is set. When the RSI\_DAT0 line goes high, CARDRDY bit of RSI\_STAT0 register is set and BUSYMODE bit is cleared. CARDRDY interrupt is also raised. The CARDRDY bit is a W1C bit and can be cleared by writing 1. If the RSI\_DAT0 doesn't go low at the third cycle from the end bit of the command, card is considered as not busy. BUSYMODE bit of RSI exception status register won't be set, CARDRDY interrupt is raised and CARDRDY bit is set. If the CHKBUSY bit in RSI\_CMD register is not enabled, the RSI\_DAT0 pin is not checked for busy condition.

BUSYMODE bit is also updated during data write operation if the RSI\_DAT0 is pulled low while card is programming the data. But CARDRDY bit and CARDRDY interrupt are not updated for this case.

## SDIO Support

Two additional RSI features implement SDIO functionality.

- Hardware interrupt support over the RSI\_DATA1 pin
- Read wait request over the RSI\_DATA2 pin

SDIO devices may have multiple interrupt sources that are mapped to a single interrupt line. The interrupt is level-sensitive, allowing multiple functions to generate an interrupt simultaneously. Thus the interrupt request will continually be asserted until all sources generating an interrupt are determined and cleared by the RSI.

The sources of the interrupts are found by interrogating the SDIO device. The interrupts are cleared through operations unique to each function.

The SDIO device sends an interrupt request to the RSI by asserting the RSI\_DATA1 signal low. The interrupt status is indicated by the SDIOINT bit of the RSI\_STAT0 register. The status can be configured to interrupt the processor through the SDIOINT bit of the RSI\_IMSK0 register.

When the RSI is configured for 1-bit bus width, the interrupt is generated by the SDIO with no timing constraints since the RSI\_DATA1 signal acts as a dedicated IRQ signal. The RSI should be configured using RSI\_CFG such that pull-up are enabled on all RSI\_DATAx signals. When the RSI sampling RSI\_DATA1 low, the RSI asserts the SDIOINT flag. This flag is asserted until the RSI\_DATA1 signal is sampled high again.

When the RSI is configured for 4-bit bus widths, the RSI\_DATA1 signal is shared between the IRQ signal and the RSI\_DATA1 signal. In this configuration, the interrupt is only be recognized by the RSI within a specific interrupt period.

## RSI Block Diagram

The figure shows the functional blocks within the RSI.

**Figure 24-5:** RSI Block Diagram

## RSI Signal Descriptions

The RSI is a 10 pin interface out of which one pin is used for clock, one pin for command and the rest of the 8 pins are used for data. The [RSI Signal Descriptions \(general\)](#) table "RSI Signal Descriptions (general)" shows a general functional description of various RSI signals.

**Table 24-14:** RSI Signal Descriptions (general)

| Signal Name | Signal Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RSI_CLK     | The clock signal applied to the card from the RSI. All command and data signal transfers are synchronous to this clock. The frequency can vary between zero and the maximum clock frequency. Refer to the respective processor data sheet for the maximum supported clock frequency.                                                                                                                                                                                                                                                |
| RSI_CMD     | A bi-directional command signal used for command transfer and card initialization. The RSI uses this signal to send commands to the cards, and the card uses the signal to send responses back to the RSI. This signal can be configured for both push-pull mode and open-drain mode, but only MMC cards support the open-drain mode. The open-drain mode allows for multiple MMC cards to share data and command signals on the RSI interface and allows for the initialization sequence to take place on all cards <sup>1</sup> . |
| RSI_DATAx   | These are the configurable bi-directional data channels used for all data transfers both to and from the card. The data bus width can be configured as 1-, 4-, or 8-bit.                                                                                                                                                                                                                                                                                                                                                            |

Notes:

1. Although earlier revisions of the MMC specifications allowed for multiple MMC cards to be bused to a single RSI interface, it is strongly recommended that only a single device be interfaced to any given RSI interface. Multiple devices sharing a single command and data bus is now actively discouraged by the device specifications.

The table "RSI Signal Descriptions (MMC and CE-ATA)" and describes the functionality of these signals for MMC and CE-ATA protocols and the table "RSI Signal Descriptions (SD and SDIO)" describes the functionality of these signals for SD and SDIO protocols.

**Table 24-15:** RSI Signal Descriptions (MMC and CE-ATA)

## RSI Architectural Concepts

The following sections describe the functions and features of the RSI controller as well as the MMC, SD, SDIO, and CE-ATA protocols. For detailed information on timing parameters and protocol requirements, refer to the corresponding processor data sheet and the following standards and specifications.

- MMCA System Specification
- JESD84 series of JEDEC standards
- SD Specifications Part 1 Physical Layer Specification
- SD Specifications Part 1 Physical Layer Simplified Specification
- SD Specifications Part E1 SDIO Specification

Communication is through a master and slave configuration, where the RSI is the master and the card is the slave device. The RSI communicates with the device using a message-based bus protocol in which the host sends commands serially using the *RSI\_CMD* signal. Some commands require that the card provide a response back to the host. This response is also sent serially by the *RSI\_CMD* signal.

Data transfers, both to and from the card, occur using the *RSI\_DATAx* signals. The number of data lines used for the data transfer can be configured to 1, 4, or 8 using *RSI\_DATA0*, *RSI\_DATA3—0*, or *RSI\_DATA7—0*. All *RSI\_CMD* and *RSI\_DATAx* transfers are synchronous with *RSI\_CLK*.

Cyclic redundancy codes (CRC) are used to protect commands, responses and data transfers from transmission errors. A CRC7 code is generated for every command sent by the host and for almost every response returned by the card on the RSI\_CMD signal. A CRC16 code is used on the RSI\_DATAx signals to protect block data transfers. In 4- and 8-bit bus configurations, CRC16 is calculated for each individual data signal.

## RSI Operating Modes

The following sections describe the functionality of the RSI module in various modes of operation.

### Card Identification Mode

When a device connected to the RSI is first powered and detected by the host or has been reset, the device must first be identified and initialized by the host. The software determines whether the device is compatible with the RSI controller and the implemented software drivers. This phase in the procedure is known commonly as the card identification mode.

When a device is in card identification mode, the host may be required to perform the following actions.

- Reset the device
- Validate the device operating voltage range
- Identify the device type
- Assign/request a relative card address (RCA)

All communications between the host and card during the card identification phase occur using the RSI\_CMD signal. The maximum clock frequency during the identification phase is typically far lower than the maximum data transfer frequency for the card.

### Data Transfer Mode

The card enters stand-by state, known as the data transfer mode, when it has been assigned an RCA. Data transfers can only take place when the device has entered the data transfer mode.

Once the device is in data transfer mode, communication takes place through the RSI\_CMD and the RSI\_DATAx signals. The card is further interrogated to identify bus widths, maximum clock frequency, and the device capacity. At this point the bus width can be altered and the clock frequency can be increased.

Data may be written to the device or read from the device using the following two methods.

- Stream reads and writes
- Block reads and writes

Stream transfers produce a continuous stream of data until the RSI stops the transfer by setting a specific command.

For stream read and write operations, additional maximum operating frequency limitations may be imposed by the device. Stream write operations may also have restrictions that are dependent upon writable block boundaries.

Block based transfers result in a block of a pre-configured size being transferred. The block size depends on the device and is obtained by reading registers contained on the device during the device detection procedure.

The data transfer between the RSI block and the processor's internal memory can be performed in two ways as described below.

## DMA Data Transfers

The RSI block has a dedicated DMA channel assigned. This DMA channel can be configured either to transmit/receive the data from/to the RSI data FIFO without core intervention.

## Core Data Transfers

If the RSI DMA channel is disabled, the RSI transmit/receive FIFO may be written or read by the processor core as a memory-mapped register (RSI\_FIFO). In order to avoid FIFO overflow or underflow, the core should access the FIFO registers in one of the two following ways.

1. Unmask the transmit FIFO empty (TXFIFOZERO) or receive FIFO full (RXFIFOFULL) interrupt in the RSI\_XFR\_IMSK0/1 register. Write the word to be set out to the transmit FIFO or read the received word from the receive FIFO inside the interrupt service routine.
2. Poll the transmit FIFO empty (TXFIFOZERO) or receive FIFO full (RXFIFOFULL) status bit in the RSI\_XFR\_STAT register. Write the word to be set out to the transmit FIFO or read the received word from the receive FIFO after the corresponding status bit is detected as set.

## Boot Mode

MultiMedia Cards (MMC) based on the MMCA specifications version 4.3 or later support a special mode known as boot mode. In this mode, the MMC host can read boot data from the slave MMC device by keeping RSI\_CMD line low after power-on, or sending CMD0 with argument 0xFFFFFFFF (optional for slave), before issuing CMD1. The data can be read from either a dedicated boot area or user area.

## Normal Boot Mode

Before enabling the RSI boot, boot timing counters (SETUP and HOLD) in the RSI\_BOOT\_TCNTR register and boot mode type (MMCBMODE) in the RSI\_CFG register should be programmed. Otherwise RSI will use the default values of 74 and 56 RSI\_CLK cycles. DATA\_TMR register should be programmed to act as boot data timeout register. If the BACKEN bit of the RSI\_CFG register is set, boot acknowledge timeout (RSI\_BACK\_TOUT) register should also be programmed. For normal boot mode, MMCBMODE bit in RSI\_CFG register is written 0.

When the RSI block is enabled for normal boot mode, by setting the MMCBEN bit of the RSI\_CFG register, following tasks are done at the same cycle.

1. RSI\_CMD line is pulled low.
2. Boot setup counter (RSI\_BOOT\_TCNTR) starts decrementing.
3. Boot acknowledge timeout (RSI\_BACK\_TOUT) counter starts incrementing if the BACKEN bit is set.
4. Boot data timeout counter (DATA\_TMR) starts incrementing.

When the boot setup counter expires, BSETUPEXP interrupt is raised and also BSETUPEXP bit of RSI\_STAT0 register will be set. BSETUPEXP interrupt indicates that card has entered the boot state. Core can clear this status bit by writing 1 to BSETUPEXP bit of RSI\_STAT0 register. Clearing this bit also clears the BSETUPEXP interrupt line.

If BACKEN bit is set in RSI\_CFG register, the RSI goes to boot state and expects an acknowledgement to be returned by the slave within an interval as programmed in RSI\_BACK\_TOUT counter. If this acknowledge is not received before the counter reaches this value, BACKTO interrupt is raised and also BACKTO bit of RSI\_STAT0 register is set. If the acknowledge is received, but is not “010”, BACKBAD interrupt is raised and also BACKBAD of RSI\_STAT0 register is set. In both the above cases RSI goes back to IDLE state. Core can clear the status bits by writing 1 to RSI\_STAT0 register. Core should terminate the boot operation by pulling RSI\_CMD line high by writing 0 to MMCBEN bit of RSI\_CFG register. Now boot hold counter (RSI\_BOOT\_TCNTR) starts decrementing. Once the counter expires, BHOLDEXP interrupt is raised and BHOLDEXP bit of RSI\_STAT0 register will be set. Core can clear this status bit by writing 1 to the same bit. From here RSI can start normal operation (non boot operation even though boot operation failed).

If the acknowledge is received before the RSI\_BACK\_TOUT counter expires, RSI enters WAIT\_R state once the data transfer is enabled by writing to RSI\_DATA\_CTL register. RSI waits for the start bit of the data.

If BACKEN bit is 0 in the RSI\_CFG register, then no acknowledgement is expected and RSI is in WAIT\_R state once the data transfer is enabled by writing to RSI\_DATA\_CTL register.

Slave should start sending the boot data before boot data timeout (DATA\_TMR) counter expires. If the counter expires while state machine is still in WAIT\_R state, BDATTO interrupt is raised and also BDATTO bit is set. Core can clear this bit by writing 1 to bit 10 of the bit of the RSI\_STAT0 register. RSI goes to IDLE state after timeout.

Once the entire boot data is received, core can terminate the boot operation by pulling RSI\_CMD line high by writing 0 to MMCBEN bit of RSI\_CFG register. Now boot hold counter (RSI\_BOOT\_TCNTR) starts decre-

menting. Once the counter expires, BHOLDEXP interrupt is raised and also BHOLDEXP bit of RSI\_STAT0 register will be set. Core can clear this status bit by writing 1 to the same bit. From here, RSI can start normal operation (non boot operation even though boot operation failed).

Now the slave is ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

## Alternate Boot Mode

Before enabling the RSI boot, boot timing counters (SETUP and HOLD) in the RSI\_BOOT\_TCNTR register and boot mode type (MMCBMODE) in the RSI\_CFG register should be programmed. Otherwise RSI uses the default values of 74 and 56 RSI\_CLK cycles. DATA\_TMR register should be programmed to act as boot data timeout register. If the BACKEN bit of the RSI\_CFG register is set, boot acknowledge timeout (RSI\_BACK\_TOUT) register should also be programmed. For alternate boot mode, MMCBMODE bit in RSI\_CFG register is written 1.

When the RSI block is enabled for alternate boot mode, by setting the MMCBEN bit of the RSI\_CFG register, Boot setup counter (RSI\_BOOT\_TCNTR) starts decrementing. When this counter expires, BSETUPEXP interrupt is raised and also status bit BSETUPEXP will be set in the RSI\_STAT0 register. Core can clear this status bit by writing 1 to the same bit. Only after getting BSETUPEXP interrupt, CMD0 with argument 0xFFFFFFFFFA should be sent to slave to start the boot operation. When the end bit of this CMD0 is reached on the CMD line, boot acknowledge timeout counter (RSI\_BACK\_TOUT) and boot data timeout counter (DATA\_TMR) start incrementing from zero.

If BACKEN bit is set in RSI\_CFG register, the RSI goes to boot state and expects an acknowledgement to be returned by the slave within an interval as programmed in RSI\_BACK\_TOUT counter. If this acknowledge is not received before the counter expires, BACKTO interrupt is raised and also status bit BACKTO is set in RSI\_STAT0 register. If the acknowledge is received, but is not "010", BACKBAD interrupt is raised and also status bit BACKBAD is set. In both the above cases RSI goes back to IDLE state. Core can clear the status bits by writing 1 to respective bits of RSI\_STAT0 register.

Core can terminate the boot operation first by clearing the MMCBEN bit of RSI\_CFG register and then sending CMD0 command. Now boot hold counter (RSI\_BOOT\_TCNTR) starts decrementing. Once the counter expires, BHOLDEXP interrupt is raised and also status bit BHOLDEXP will be set. Core can clear this status bit by writing 1 to RSI\_STAT0 register. From here, RSI can start normal operation (non boot operation even though boot operation failed).

If the acknowledge is received before the RSI\_BACK\_TOUT counter expires, RSI enters WAIT\_R state once the data transfer is enabled by writing to RSI\_DATA\_CTL register. RSI waits for the start bit of the data.

If BACKEN bit is 0 in the RSI\_CFG register, then no acknowledgement is expected and RSI is in WAIT\_R state once the data transfer is enabled by writing to RSI\_DATA\_CTL register.

Slave should start sending the boot data before boot data timeout counter (DATA\_TMR) expires. If the counter expires while state machine is still in WAIT\_R state, BDATTO interrupt is raised and also BDATTO flag is set. Core can clear this bit by writing 1 to the same bit. RSI goes to IDLE state after timeout.

When the entire boot data is received, core can terminate the boot operation by clearing `MMCBEN` bit of `RSI_CFG` register and sending `CMD0` command. Now boot hold counter (`RSI_BOOT_TCNT`) starts decrementing. Once the counter expires, `BHOLDEXP` interrupt is raised and also status bit `BHOLDEXP` will be set. Core can clear this status bit by writing 1 to `BHOLDEXP` bit `RSI_STAT0` register. From here, RSI can start normal operation (non boot operation even though boot operation failed).

Now the slave is ready for `CMD1` operation and the master needs to start a normal MMC initialization sequence by sending `CMD1`.

Note: If Boot is abruptly terminated for whatever reason, booting cannot be retried without power off and power on to the MMC card.

## Sleep Mode

MultiMedia Cards (MMC) based on the MMCA specification version 4.3 or later support this mode. A card may be switched between a sleep state and a standby state by `SLEEP/WAKEUP` command (`CMD5`). In the sleep state, the power consumption of the memory device is minimized. The `SLEEP` command is used to initiate the state transition from standby state to sleep state. The memory device indicates the transition phase busy by pulling the `RSI_DATA0` line low. The sleep state is reached when the memory device stops pulling down the `RSI_DATA0` line low (`RSI_DATA0` goes high).

The `WAKEUP` command is used to initiate the state transition from sleep state to standby state. The memory device indicates the transition phase busy by pulling down the `RSI_DATA0` line low. The standby state is reached when the memory device stops pulling down the `RSI_DATA0` line low (`RSI_DATA0` goes high).

When in standby state, card is allowed to go to sleep mode by sending the `CMD5` with bit 15 set in argument. `SLP_WKUP_TOUT` counter starts decrementing at the end bit of this command. RSI block is now waiting for a rising edge on the `RSI_DATA0` line. If the rising edge is not detected on the `RSI_DATA0` line before the counter expires, `SLPWKPTOUT` interrupt is raised. Also `SLPWKPTOUT` bit of `RSI_STAT0` register is set.

If a rising edge is detected on `RSI_DATA0` pin before the `SLP_WKUP_TOUT` counter expires, `SLPDONE` interrupt is raised and also `SLPDONE` bit and `SLPMODE` bit of `RSI_STAT0` register are set. This indicates that card has successfully entered sleep state. `SLPDONE` bit is a W1C bit and can be cleared by writing 1. `SLPMODE` bit is a read-only bit and can not be cleared by writing 1. Now the `Vcc` power supply for the card may be switched off. The `Vcc` supply have to be ramped back up before the state transition from the sleep state to standby state initiated by sending the `WAKEUP` command.

When the `WAKEUP` command is issued by sending `CMD5` with bit 15 as 0 in argument, `SLP_WKUP_TOUT` counter starts decrementing. If a rising edge on the `RSI_DATA0` line is not detected before the counter expires, `SLPWKPTOUT` interrupt is raised. Also `SLPWKPTOUT` bit of `RSI_STAT0` register is set.

If a rising edge is detected on `RSI_DATA0` pin before the counter expires, `WKPDONE` interrupt is raised and `WKPDONE` bit of `RSI_STAT0` register is set and `SLPMODE` bit of `RSI_STAT0` register is cleared. This indicates that card has successfully entered standby state. Now normal operation can be resumed.

A SLEEP command is recognized only if the card is in the standby state and the WAKEUP command is recognized only when the card is in the sleep state.

## RSI Data Transfer Modes

{Editor's note: This topic is an optional, example topic. If it does not apply to the module, deleted it. If it does apply to the module, please keep it, retain this name for it, and have it appear in this location in the chapter.}

## RSI Signal Modes

{Editor's note: This topic is an optional, example topic. If it does not apply to the module, deleted it. If it does apply to the module, please keep it, retain this name for it, and have it appear in this location in the chapter.}

## RSI Event Control

This section provides details about various RSI interrupt, status, and error signals.

## RSI Interrupt Signals

The RSI has two interrupt signals (IRQ0 and IRQ1) which connect the module to the System Event Controller (SEC).

## RSI Status and Error Signals

The RSI block has 22 individual status bits in the `RSI_XFRSTAT` register that can be configured to generate an interrupt. The status bits can be mapped to either of the two interrupts IRQ0 or IRQ1. This allows for greater flexibility in system configuration. To generate an interrupt on IRQ0, the interrupt should be enabled by setting the corresponding bit in the `RSI_XFR_IMSK0` register. Interrupts that are required to be generated on IRQ1 are enabled by setting the corresponding bit in the `RSI_XFR_IMSK1` register.

In addition the `RSI_XFRSTAT` register, each of the flags in the `RSI_STAT0` register are also capable of generating an interrupt. Interrupts for the `RSI_STAT0` flags are enabled by setting the corresponding bit in the `RSI_IMSK0` register. These interrupts are sent to the SEC through IRQ0 only.

## RSI Programming Model

The following sections describe the RSI programming model for various RSI operating modes.

## Card Identification

### SD Card Identification Procedure

1. Issue the IDLE command to the card using the `RSI_CMD` register.
2. Issue the SEND\_IF command through the `RSI_CMD` register, supplying the host supply voltage and a check pattern via the `RSI_ARG` register. The command expects an R7 response type. If a valid response with a compatible voltage range and matching check pattern is received, the card is compliant with SD vSDHon 2.00 or later. If a response is received with an incompatible voltage range the card cannot be used. If no response is received at all, as indicated by the `CMDTO` flag on the `RSI_XFRSTAT` register, go to step 5.
3. Issue the `RSI_SEND_OP_COND` command through the `RSI_CMD` register, supplying the voltage window supported and whether the host supports high capacity cards using the `RSI_ARG` register. The RSI expects an R3 response to this command. The RSI can reject the card at this point if the voltage range is not compatible. If the card returns a response indicating that it is busy, resend the `RSI_SEND_OP_CMD` until the card indicates it is ready. If the host does not support the high capacity mode as indicated by setting the HCS bit of the argument to 0—a high capacity card never clears the busy status bit. The card should be identified within one second. If in that time the card is still bus, or no valid responses have been received, the card is rejected.
4. If the host supports high-capacity cards, verify whether the response in the `RSI_RESP0` register indicates that the card capacity status (CCS) bit is set. If CCS is set, an SD VeSDHon 2.00 or later high capacity SD memory card is present—proceed to step 6.
5. If the CCS bit is cleared, then the card is an SD VeSDHon 2.00 or later standard capacity memory card— proceed to step 6. Issue the `RSI_SEND_OP_COND` command via the `RSI_CMD` register, supplying the voltage window supported and with the high-capacity support (HCS) bit set to 0 via the `RSI_ARG` register. The RSI expects an R3 response to this command, at which time the card can be rejected if the voltage range is not compatible. If the card returns a response indicating that it is busy, resend the `RSI_SEND_OP_CMD` until the card indicates that it is ready. The card should be identified within 1 second. If in that time frame the card is still busy or no valid responses have been received, the card should be rejected. Once the response indicates that the card is ready, the card type has been identified as an SD Version 1.x standard-capacity memory card.
6. Issue the `ALL_SEND_CID` command to which an R2 response type is expected. This will result in the card sending the 128-bit card identification (CID) register and transitioning from ready to identification mode.
7. Issue the `SEND_RELATIVE_ADDR` command to which an R6 response type is expected. This will result in the card issuing a new relative address which must be used in order to select the card in the future for data transfers. The card will then move into standby mode completing the identification procedure.

## MMC Card Identification Procedure

1. Issue the IDLE command to the card via the `RSI_CMD` register.
2. Issue the `SEND_OP_COND` command to the card via the `RSI_CMD` register, supplying the operating voltage window that the host is compatible with and the access mode that the host supports (byte or sector) via the `RSI_ARG` register. The RSI expects an R3 type response. This allows the host to reject the card if it is not compatible with the supply voltage or if the access mode is not supported by the host software. If the card returns an indication that it is busy, repeat this step until the card is either rejected or not busy.
3. Issue the `ALL_SEND_CID` command via the `RSI_CMD` register. The RSI expects an R2 response to this command. This will result in the card sending the 128-bit card identification (CID) register and transitioning from ready to identification mode.
4. Issue the `SET_RELATIVE_ADDR` command, providing a 16-bit relative card address (RCA) via the `RSI_ARG` register that will get assigned to the card. An R1 response type is expected for this command. This will result in the card being assigned with the provided RCA, which must be used in order to select the card in the future for data transfers. The card will then move into standby mode, completing the identification procedure.

## Data transfer

The following section describe how to program the RSI block for various data transfer scenarios in both core and DMA modes.

### Single Block Write

Block write operations typically consist of 512 bytes of data per block. If the card is found to support other block lengths or the default block length as specified in the CID register is not 512, the block length of the RSI must be configured accordingly. The block length of the card and the block length of the RSI must be configured for the same block size at all times. The block length of the RSI is configured via the `RSI_BLKSZ` register.

NOTE: It is important to pay attention as to when the data path state machine is enabled and when data is written to the FIFO for transfer to the card. Write transactions require that data be written after the response has completed for the `WRITE_BLOCK` command. If the data path state machine is enabled prior to sending the `WRITE_BLOCK` command, data must not be written to the transmit FIFO via the DMA or core until after the response has been received as indicated by the `RESPEND` flag of the `RSI_XFRSTAT` register. Failure to adhere to this procedure can result in data being written to the card in violation to the block write timing parameters, resulting in a data CRC failure.

## Using Core

1. Write the `RSI_ARG` register with the cards RCA. The 16-bit RCA should be written to the upper 16-bits of the `RSI_ARG` register.
2. Write the `RSI_CMD` register with the `SELECT/DESELECT_CARD` command, configuring the command path state machine to expect a short response by setting `RSP` and clearing `LRSP`. The response type is `R1b`.
3. Wait for the `RESPEND` indication within the `RSI_XFRSTAT` register and clear the status bit once detected via the `RSI_XFRSTAT_CLR` register.
4. Ensure that the device is not busy and no errors occurred by verifying the response contained in `RSI_RESP0`.
5. Write the number of bytes to be transferred to the `RSI_DATA_LEN` register. This will be 512 bytes for a single block.
6. Write the appropriate timeout value for a write operation to the `RSI_DATA_TMR` register.
7. Write the destination start address to the `RSI_ARG` register. The supplied address must be aligned to a 512 byte boundary if misaligned accesses are not enabled and the card is not a high-capacity SD card or sector-addressable MMC card.
8. Write the `WRITE_BLOCK` command to the `RSI_CMD` register, configuring the command path state machine to expect a short response by setting `RSP` and clearing `LRSP`. The response type is `R1`.
9. Wait for the `RESPEND` indication within the `RSI_XFRSTAT` register and clear the status bit once detected via the `RSI_XFRSTAT_CLR` register.
10. Enable the data path state machine by writing to the `RSI_DATA_CTL` register with `RSI_BLKSZ` set to 512 for a 512-byte block. `DATEN` should also be set to enable the data path state machine. All other fields of the `RSI_DATA_CTL` register should be zero.
11. Write data to the `RSI_FIFO` register until the FIFO becomes full as indicated by the `TXFIFOFULL` flag of the `RSI_XFRSTAT` register. Continue to write data to the FIFO as long as the FIFO is not full or write data in blocks of eight 32-bit words if polling on the `TXFIFOSTAT` bit indicating the transmit FIFO is half empty. Continue until all 128 32-bit words (512 bytes) have been transferred.
12. Wait for the card to respond with the CRC token by waiting for the `DATBLKEND` flag to be set. `DATEND` will also be set at this time if the `RSI_DATA_LEN` register was set to 512 bytes in step 5.
13. Clear the `DATBLKEND` and `DATEND` flags via the `RSI_XFRSTAT_CLR` register.

## Using DMA

1. Write the `RSI_ARG` register with the cards RCA. The 16-bit RCA should be written to the upper 16-bits of the `RSI_ARG` register.
2. Write the `RSI_CMD` register with the `SELECT/DESELECT_CARD` command, configuring the command path state machine to expect a short response by setting `RSP` and clearing `LRSP`. The response type is `R1b`.
3. Wait for the `RESPEND` indication within the `RSI_XFRSTAT` register, and clear the status bit once detected via the `RSI_XFRSTAT_CLR` register.
4. Ensure that the device is not busy and no errors occurred by verifying the response contained in `RSI_RESP0`. Configure the DMA channel assigned to the RSI controller.
5. Write `DMAx_ADDRSTART` with the address of the first byte of data to be written to the card. The `DMAx_XCNT` register should be set to 128, and the `DMAx_XMOD` register to 4. The `DMAx_CFG` register should be set for DMA enable (a word size of 32-bits).
6. Once the DMA channel has been configured and enabled, write the number of bytes to be transferred to the `RSI_DATA_LEN` register. This will be 512 bytes for a single block.
7. Write the appropriate timeout value for a write operation to the `RSI_DATA_TMR` register.
8. Write the destination start address to the `RSI_ARG` register. The address supplied must be aligned to a 512-byte boundary if misaligned accesses are not enabled and the card is not a high-capacity SD card or sector-addressable MMC card.
9. Write the `WRITE_BLOCK` command to `RSI_CMD`, configuring the command path state machine to expect a short response by setting `RSP` and clearing `LRSP`. The response type is `R1`.
10. Wait for the `RESPEND` indication within the `RSI_XFRSTAT` register, and clear the status bit once detected via the `RSI_XFRSTAT_CLR` register.
11. Enable the data path state machine by writing to the `RSI_DATA_CTL` register with `RSI_BLKSZ` set to 512 for a 512-byte block. `DATEN` and `DMAEN` should also be set to enable the data path state machine and to allow the DMA controller to access the transmit FIFO. All other fields of the `RSI_DATA_CTL` register should be zero.
12. Wait for the card to respond with the CRC token by waiting for the `DATBLKEND` flag to be set. `DATEND` will also be set at this point if the `RSI_DATA_LEN` register was set to 512 bytes in step 5.
13. Clear the `DATBLKEND` and `DATEND` flags via the `RSI_XFRSTAT_CLR` register. Also clear the `IRQDONE` bit of the `DMAx_STAT` register, if applicable.

## Single Block Read

Block read operations typically consist of 512 bytes of data per block. If the card is found to support other block lengths or the default block length as specified in the CID register is not 512, the block length of the RSI must be configured accordingly. The block length of the card and the block length of the RSI must be

configured for the same block size at all times. The block length of the RSI is configured via the `RSI_BLKSZ` register.

NOTE: It is important to pay attention as to when the data path state machine is enabled and when data is read from the receive FIFO for data transfers from the card to the RSI. Read transactions can occur on the `RSI_DATAx` signals prior to the response of the command being received. It is therefore advisable to enable the data path state machine, and DMA controller if being used, either:

- Prior to issuing a command that involves a data read packet
- Immediately after the command has been issued but prior to pending on the `RESPEND` flag

NOTE: If the core is being used to read the receive FIFO, it is advised not to pend on the `RESPEND` flag. It is possible for data to be driven on the `RSI_DATAx` signals two `RSI_CLK` cycles after the end bit of the command. At minimum, an additional 48 `RSI_CLK` cycles will pass before the response is received, during which time the receive buffer may potentially have received 24 bytes of data on a 4-bit bus and will be approaching the half full state. Software should ensure that the receive buffer does not become full prior to data being read from the receive FIFO.

## Using Core

1. Write the `RSI_ARG` register with the cards RCA. The 16-bit RCA should be written to the upper 16-bits of the `RSI_ARG` register.
2. Write the `RSI_CMD` register with the `SELECT/DESELECT_CARD` command, configuring the command path state machine to expect a short response by setting `RSP` and clearing `LRSP`. The response type is `R1b`.
3. Wait for the `RESPEND` indication within the `RSI_XFRSTAT` register and clear the status bit once detected via the `RSI_XFRSTAT_CLR` register.
4. Ensure that the device is not busy and no errors occurred by verifying the response contained in `RSI_RESP0`.
5. Write the number of bytes to be transferred to the `RSI_DATA_LEN` register. This will be 512 bytes for a single block.
6. Write the appropriate timeout value for a read operation to the `RSI_DATA_TMR` register.
7. Write the destination start address to the `RSI_ARG` register. The address supplied must be aligned to a 512-byte boundary if misaligned accesses are not enabled and the card is not a high-capacity SD card or sector-addressable MMC card.
8. Enable the data path state machine by writing to the `RSI_DATA_CTL` register with `RSI_BLKSZ` set to 512 for a 512-byte block. `DATEN` and `DATDIR` should also be set to enable the data path state machine and indicate the transfer direction is from card to controller. All other fields of the `RSI_DATA_CTL` register should be zero.
9. Write the `READ_SINGLE_BLOCK` command to the `RSI_CMD` register, configuring the command path state machine to expect a short response by setting `RSP` and clearing `LRSP`. The response type is `R1`.

10. In order to meet some timing restrictions related to block read operations, it is advisable to not wait for the `RESPEND` indication within the `RSI_XFRSTAT` register but instead move immediately on the next step. This is due to the card being able to send data before a response can be completed on the `RSI_CMD` signal, moving immediately onto step 11 will ensure a receive FIFO overflow does not occur.
11. Poll the `RXFIFORDY` bit or the `RXDATZERO` bit of `RSI_XFRSTAT` indicating the receive FIFO has data available, or the receive FIFO is empty. As long as the receive FIFO is not empty, read data from the `RSI_FIFO` register until all 512 bytes have been read.
12. Once all bytes have been read, wait for the `DATBLKEND` flag to indicate that the data was received correctly and passed the CRC check. The `DATEND` flag may also be set, depending on the value written to `RSI_DATA_LEN`.
13. Clear the `DATBLKEND` and `DATEND` flags via the `RSI_XFRSTAT_CLR` register.

## Using DMA

1. Write the `RSI_ARG` register with the card's RCA. The 16-bit RCA should be written to the upper 16-bits of the `RSI_ARG` register.
2. Write the `RSI_CMD` register with the `SELECT/DESELECT_CARD` command, configuring the command path state machine to expect a short response by setting `RSP` and clearing `LRSP`. The response type is `R1b`.
3. Wait for the `RESPEND` indication within the `RSI_XFRSTAT` register, and clear the status bit once detected via the `RSI_XFRSTAT_CLR` register.
4. Ensure that the device is not busy and no errors occurred by verifying the response contained in `RSI_RESP0`.
5. Configure the DMA channel assigned to the RSI controller. Write `DMAx_ADDRSTART` with the address of the first byte of where the received data is to be stored. The `DMAx_XCNT` register should be set to 128 and the `DMAx_XMOD` register to 4. The `DMAx_CFG` register should be set for DMA enable (a word size of 32-bits and direction set to memory write).
6. Write the number of bytes to be transferred to the `RSI_DATA_LEN` register. This will be 512 bytes for a single block.
7. Write the appropriate timeout value for a read operation to the `RSI_DATA_TMR` register.
8. Write the source start address to the `RSI_ARG` register. The supplied address must be aligned to a 512-byte boundary if misaligned accesses are not enabled and the card is not a high-capacity SD card or sector-addressable MMC card.
9. Enable the data path state machine by writing to the `RSI_DATA_CTL` register with `RSI_BLKSZ` set to 512 for a 512-byte block. `DATEN`, `DATDIR`, and `DMAEN` should also be set to enable the data path state machine, set the transfer direction from card to controller and allow the DMA controller access to the receive FIFO. All other fields of the `RSI_DATA_CTL` register should be zero.

10. Write the READ\_SINGLE\_BLOCK command to the RSI\_CMD register, configuring the command path state machine to expect a short response by setting RSP and clearing LRSP. The response type is R1.
11. Unlike core accesses, it is safe to poll on RESPEND indication within the RSI\_XFRSTAT register and clear the status bit once detected via the RSI\_XFRSTAT\_CLR register. The DMA controller enabled in step 5 will ensure any data sent to the receive FIFO prior to the RESPEND flag being set is received correctly.
12. Wait for the DATBLKEND flag to indicate that the data was received correctly and passed the CRC check. The DATEND flag may also be set, depending on the value written to RSI\_DATA\_LEN.
13. Clear the DATBLKEND and DATEND flags via the RSI\_XFRSTAT\_CLR register. Also clear the IRQDONE bit of the DMAX\_STAT register, if applicable.

## Multiple Block Write

Block write operations typically consist of 512 bytes of data per block. If the card is found to support other block lengths or the default block length as specified in the CID register is not 512, the block length of the RSI must be configured accordingly. The block length of the card and the block length of the RSI must be configured for the same block size at all times. The block length of the RSI is configured via the RSI\_BLK SZ field of the RSI\_DATA\_CTL register.

## Using Core

1. Write the RSI\_ARG register with the cards RCA. The 16-bit RCA should be written to the upper 16-bits of the RSI\_ARG register.
2. Write the RSI\_CMD register with the SELECT/DESELECT\_CARD command, configuring the command path state machine to expect a short response by setting RSP and clearing LRSP. The response type is R1b.
3. Wait for the RESPEND indication within the RSI\_XFRSTAT register and clear the status bit once detected via the RSI\_XFRSTAT\_CLR register.
4. Ensure that the device is not busy and no errors occurred by verifying the response contained in RSI\_RESP0.
5. Write the number of bytes to be transferred to the RSI\_DATA\_LEN register. For example, write 4096 to write eight blocks of 512 bytes.
6. Write the appropriate timeout value for a write operation to the RSI\_DATA\_TMR register.
7. Write the destination start address to the RSI\_ARG register. The supplied address must be aligned to a 512-byte boundary if misaligned accesses are not enabled and the card is not a high-capacity SD card or a sector-addressable MMC card.
8. Write the WRITE\_MULTIPLE\_BLOCK command to RSI\_CMD, configuring the command path state machine to expect a short response by setting RSP and clearing LRSP. The response type is R1.

9. Wait for the RESPEND indication within the RSI\_XFRSTAT register, and clear the status bit once detected via the RSI\_XFRSTAT\_CLR register.
10. Enable the data path state machine by writing to the RSI\_DATA\_CTL register with RSI\_BLK SZ set to 512 for a 512-byte block. DATEN should also be set to enable the data path state machine. All other fields of the RSI\_DATA\_CTL register should be zero.
11. Write data to the RSI\_FIFO register until the FIFO becomes full as indicated by the TXFIFOFULL flag of the RSI\_XFRSTAT register. Continue to write data to the FIFO as long as the FIFO is not full or write data in blocks of eight 32-bit words if polling on the TXFIFOSTAT bit indicating the transmit FIFO is half empty. Continue until all 128 32-bit words (512 bytes) have been transferred.
12. Wait for the card to respond with the CRC token by waiting for the DATBLKEND flag to be set.
13. Clear the DATBLKEND flag.
14. Repeat steps 11 to 13 for the number of blocks to be transferred or until DATEND flag is set.
15. Write the RSI\_CMD register with the STOP\_TRANSMISSION command, configuring the command path state machine to expect a short response by setting RSP and clearing LRSP. The response type is R1. 16.
16. Clear the DATEND and RESPEND flags via the RSI\_XFRSTAT\_CLR register.

## Using DMA

1. Write the RSI\_ARG register with the cards RCA. The 16-bit RCA should be written to the upper 16-bits of the RSI\_ARG register.
2. Write the RSI\_CMD register with the SELECT/DESELECT\_CARD command, configuring the command path state machine to expect a short response by setting RSP and clearing LRSP. The response type is R1b.
3. Wait for the RESPEND indication within the RSI\_XFRSTAT register, and clear the status bit once detected via the RSI\_XFRSTAT\_CLR register.
4. Ensure that the device is not busy and no errors occurred by verifying the response contained in RSI\_RESP0.
5. Configure the DMA channel assigned to the RSI controller. Write DMAx\_ADDRSTART with the address of the first byte of data to be written to the card. The DMAx\_XCNT register should be set to the overall number of 32-bit words to be written; for example, write 1024 to transfer 4096 bytes. The DMAx\_XMOD register should be set to 4. The DMAx\_CFG register should be set for DMA enable and a word size of 32-bits.
6. Once the DMA channel has been configured and enabled, write the number of bytes to be transferred to the RSI\_DATA\_LEN register. For example, write 4096 to write eight blocks of 512 bytes.
7. Write the appropriate timeout value for a write operation to the RSI\_DATA\_TMR register.

8. Write the destination start address to the `RSI_ARG` register. The supplied address must be aligned to a 512-byte boundary if misaligned accesses are not enabled and the card is not a high-capacity SD card or sector addressable MMC card.
9. Write the `WRITE_MULTIPLE_BLOCK` command to the `RSI_CMD`, configuring the command path state machine to expect a short response by setting `RSP` and clearing `LRSP`. The response type is `R1`.
10. Wait for the `RESPEND` indication within the `RSI_XFRSTAT` register, and clear the status bit once detected via the `RSI_XFRSTAT_CLR` register.
11. Enable the data path state machine by writing to the `RSI_DATA_CTL` register with `RSI_BLKSZ` set to 512 for a 512-byte block. `DATEN` and `DMAEN` should also be set to enable the data path state machine and to allow the DMA controller to access the transmit FIFO. All other fields of the `RSI_DATA_CTL` register should be zero.
12. Poll for the `DATEND` flag or alternatively poll for each instance of the `DATBLKEND` flag that will be set on successful completion of each block transfer. For a 4096 byte transfer, `DATBLKEND` will be set eight times and should be cleared after it is detected via the `RSI_XFRSTAT_CLR` register.
13. Write the `RSI_CMD` register with the `STOP_TRANSMISSION` command, configuring the command path state machine to expect a short response by setting `RSP` and clearing `LRSP`. The response type is `R1`.
14. Clear the `DATEND` and `RESPEND` flag via the `RSI_XFRSTAT_CLR` register. Also clear the `IRQDONE` bit of the `DMAx_STAT` register, if applicable.

## Multiple Block Read

Block read operations typically consist of 512 bytes of data per block. If the card is found to support other block lengths or the default block length as specified in the CID register is not 512, the block length of the RSI must be configured accordingly. The block length of the card and the block length of the RSI must be configured for the same block size at all times. The block length of the RSI is configured via the `RSI_BLKSZ` field of the `RSI_DATA_CTL` register.

## Using the Core

1. Write the `RSI_ARG` register with the card's RCA. The 16-bit RCA should be written to the upper 16-bits of the `RSI_ARG` register.
2. Write the `RSI_CMD` register with the `SELECT/DESELECT_CARD` command, configuring the command path state machine to expect a short response by setting `RSP` and clearing `LRSP`. The response type is `R1b`.
3. Wait for the `RESPEND` indication within the `RSI_XFRSTAT` register, and clear the status bit once detected via the `RSI_XFRSTAT_CLR` register.
4. Ensure that the device is not busy and there are no errors occurred by verifying the response contained in `RSI_RESP0`.

5. Write the number of bytes to be transferred to the `RSI_DATA_LEN` register. This will be 4096 for a transfer of eight 512 byte blocks.
6. Write the appropriate timeout value for a read operation to the `RSI_DATA_TMR` register.
7. Write the destination start address to the `RSI_ARG` register. The supplied address must be aligned to a 512-byte boundary if misaligned accesses are not enabled and the card is not a high-capacity SD card or a sector-addressable MMC card.
8. Enable the data path state machine by writing to the `RSI_DATA_CTL` register with `RSI_BLKSZ` set to 512 for a 512-byte block. `DATEN` and `DATDIR` should also be set to enable the data path state machine and indicate the transfer direction is from card to controller. All other fields of the `RSI_DATA_CTL` register should be zero.
9. Write the `READ_MULTIPLE_BLOCK` command to the `RSI_CMD` register, configuring the command path state machine to expect a short response by setting `RSP` and clearing `LRSP`. The response type is `R1`.
10. In order to meet some timing restrictions related to block read operations, it is advisable to not wait for the `RESPEND` indication within the `RSI_XFRSTAT` register but instead move immediately on the next step. This is due to the card being able to send data before a response can completed on the `RSI_CMD` signal, moving immediately onto step 11 will ensure a receive FIFO overflow does not occur.
11. Poll the `RXFIFORDY` bit or the `RXFIFOZERO` bit of `RSI_XFRSTAT` indicating the receive FIFO has data available, or the receive FIFO is empty. As long as the receive FIFO is not empty, read data from the `RSI_FIFO` register until 512 bytes have been read.
12. Once the block has been read, wait for the `DATBLKEND` flag to indicate that the data was received correctly and passed the CRC check.
13. Clear the `DATBLKEND` flag via `RSI_XFRSTAT_CLR`.
14. Repeat steps 11 to 13 until the required number of blocks have been read or until the `DATEND` flag has been set.
15. Write the `RSI_CMD` register with the `STOP_TRANSMISSION` command, configuring the command path state machine to expect a short response by setting `RSP` and clearing `LRSP`. The response type is `R1`.
16. Clear the `DATEND` and `RESPEND` flags via the `RSI_XFRSTAT_CLR` register.

## Using DMA

1. Write the `RSI_ARG` register with the cards RCA. The 16-bit RCA should be written to the upper 16-bits of the `RSI_ARG` register.
2. Write the `RSI_CMD` register with the `SELECT/DESELECT_CARD` command, configuring the command path state machine to expect a short response by setting `RSP` and clearing `LRSP`. The response type is `R1b`.

3. Wait for the RESPEND indication within the RSI\_XFRSTAT register, and clear the status bit once detected via the RSI\_XFRSTAT\_CLR register.
4. Ensure that the device is not busy and that no errors occurred by verifying the response contained in RSI\_RESP0.
5. Configure the DMA channel assigned to the RSI controller. Write DMAx\_ADDRSTART with the address of the first byte of where the received data is to be stored. The DMAx\_XCNT register should be set to the number of 32-bit words to be read, which would be 1024 for a 4096 byte read transfer. The DMAx\_XMOD register should be set to 4. The DMAx\_CFG register should be set for DMA enable (a word size of 32-bits and direction set to memory write).
6. Write the number of bytes to be transferred to the RSI\_DATA\_LEN register. This will be 4096 for eight blocks of 512 bytes.
7. Write the appropriate timeout value for a read operation to the RSI\_DATA\_TMR register.
8. Write the source start address to the RSI\_ARG register. The supplied address must be aligned to a 512-byte boundary if mis-aligned accesses are not enabled and the card is not a high-capacity SD card or a sector-addressable MMC card.
9. Enable the data path state machine by writing to the RSI\_DATA\_CTL register with RSI\_BLKSZ set to 512 for a 512-byte block. DATEN, DATDIR, and DMAEN should also be set to enable the data path state machine. Set the transfer direction from card to controller and allow the DMA controller access to the receive FIFO. All other fields of the RSI\_DATA\_CTL register should be zero.
10. Write the READ\_MULTIPLE\_BLOCK command to the RSI\_CMD register, configuring the command path state machine to expect a short response by setting RSP and clearing LRSP. The response type is R1.
11. Unlike core accesses, it is safe to poll on RESPEND indication within the RSI\_XFRSTAT register and clear the status bit once detected via the RSI\_XFRSTAT\_CLR register. The DMA controller, enabled in step 5 will ensure any data sent to the receive FIFO prior to the RESPEND flag being set is received correctly.
12. Poll for the DATEND flag or alternatively poll for each instance of the DATBLKEND flag that will be set on successful completion of each block transfer. For a 4096-byte transfer, DATBLKEND will be set eight times and should be cleared after it is detected via the RSI\_XFRSTAT\_CLR register.
13. Write the RSI\_CMD register with the STOP\_TRANSMISSION command, configuring the command path state machine to expect a short response by setting RSP and clearing LRSP. The response type is R1.
14. Clear the DATEND and RESPEND flags via the RSI\_XFRSTAT\_CLR register. Also clear the IRQDONE bit of the DMAx\_STAT register, if applicable.

## RSI Programming Concepts

This section provides details about some special programming considerations to effectively use the RSI module.

## Disabling CRC check

According to specifications of memory cards such as eMMC, SDIO, and others, the cards do not send CRC for few selected commands. RSI in earlier Blackfin processors takes the stuffed bits coming from the card as CRC and gives a CRC check failure interrupt. To overcome this, a bit is added in the RSI\_CMD register where software needs to program the bit `CRCDIS` whether to disable CRC check or not.

## Data End Interrupt

In older RSI versions, DataEnd Interrupt is raised when the Data Counter reaches 0. This has been modified in the new version of RSI. DataEnd interrupt is delayed in data write operation if the card indicates a busy condition by pulling the DAT0 line low. This interrupt will be raised once the DAT0 line is released to high.

## Miscellaneous Programming Guidelines

- `PORTx_FER` bit for `RSI_CLK` should be set before `RSI_DATA3`.
- `RSI_CMD` and `RSI_DATA0` will always be used together. Therefor only one pull-up enable is used for these 2 lines.
- Write 1 to clear the SD card detect interrupt status bit, i.e bit 4 of the `RSI_STAT0` register after SDMMC reset is issued.
- There is a 2.5 system clock cycle latency involved with a write to the RSI registers. Any action that needs to be taken after the register write should be timed accordingly. This has to be specially kept in mind in scenarios where the system clock on which RSI operates is very slow compared to the core domain clock.

## RSI Programming Examples

This section is TBD

## RSI Register Descriptions

RSI (RSI) contains the following registers.

**Table 24-17:** RSI Module Registers

| Name              | Description                               |
|-------------------|-------------------------------------------|
| RSI_CTL           | Control Register                          |
| RSI_ARG           | Argument Register                         |
| RSI_CMD           | Command Register                          |
| RSI_RESP_CMD      | Response Command Register                 |
| RSI_RESP0         | Response 0 Register                       |
| RSI_RESP1         | Response 1 Register                       |
| RSI_RESP2         | Response 2 Register                       |
| RSI_RESP3         | Response 3 Register                       |
| RSI_DATA_TMR      | Data Timer Register                       |
| RSI_DATA_LEN      | Data Length Register                      |
| RSI_DATA_CTL      | Data Control Register                     |

| RSI_XFR_IMSK0     | Interrupt 0 Mask Register                 |
| RSI_XFR_IMSK1     | Interrupt 1 Mask Register                 |
| RSI_FIFO_CNT      | FIFO Counter Register                     |
| RSI_CEATA         | This register contains bit to dis CCS gen |
| RSI_BOOT_TCNTR    | Boot Timing Counter Register              |
| RSI_BACK_TOUT     | Boot Acknowledge Timeout Register         |
| RSI_SLP_WKUP_TOUT | Sleep Wakeup Timeout Register             |
| RSI_BLKSZ         | Block Size Register                       |

Table 24-17: RSI Module Registers (Continued)

| Name        | Description                        |
|-------------|------------------------------------|
| RSI_FIFO    | Data FIFO Register                 |
| RSI_STAT0   | Exception Status Register          |
| RSI_IMSK0   | Exception Mask Register            |
| RSI_CFG     | Configuration Register             |
| RSI_RD_WAIT | Read Wait Enable Register          |
| RSI_PID0    | Peripheral Identification Register |
| RSI_PID1    | Peripheral Identification Register |
| RSI_PID2    | Peripheral Identification Register |
| RSI_PID3    | Peripheral Identification Register |

Control Register

RSI\_CTL: Control Register - R/W

Reset = 0x0000

Figure 24-6: RSI\_CTL Register Diagram

**Table 24-18:** RSI\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                     |
|---------|----------|---------------------------------------------|
| 15:13   | CARDTYPE | Type of Card.                               |
|         |          | 0 SDIO                                      |
|         |          | 1 eMMC                                      |
|         |          | 1xx Reserved                                |
|         |          | 2 SD Card                                   |
|         |          | 3 CE-ATA                                    |
| 12:11   | BUSWID   | Wide Bus Mode Enable.                       |
|         |          | 0 Standard bus mode (only RSI_D0 used)      |
|         |          | 1 Wide bus mode (4bit bus)                  |
|         |          | 2 Byte bus mode (8bit bus)                  |
|         |          | 3 Reserved                                  |
| 10      | BYPASS   | Bypass clock divisor.                       |
|         |          | 0 Disable bypass                            |
|         |          | 1 Enable bypass (RSI_CLK driven from SCLK0) |
| 9       | PWRSERVE | Power Save Enable.                          |
|         |          | 0 Always Enabled                            |
|         |          | 1 Clock enabled when bus is active          |
| 8       | CLKEN    | RSI_CLK Bus Clock Enable.                   |
|         |          | 0 Disabled                                  |
|         |          | 1 Enabled                                   |
| 7:0     | CLKDIV   | RSI_CLK Divisor.                            |

Argument Register

RSI\_ARG: Argument Register - R/W

Reset = 0x0000 0000

Figure 24-7: RSI\_ARG Register Diagram

| 6       | RESPEND    | Command Response End Status. |
| 5       | RXOVER     | Receive Over run Status.     |
| 4       | TXUNDR     | Transmit Under run Status.   |
| 3       | DATTO      | Data Timeout Status.         |
| 2       | CMDTO      | CMD Timeout Status.          |
| 1       | DATCRCFAIL | Data CRC Fail Status.        |
| 0       | CMDCRCFAIL | CMD CRC Fail Status.         |

# Interrupt 0 Mask Register

RSI\_XFR\_IMSK0: Interrupt 0 Mask Register - R/W

Reset = 0x0000 0000

Figure 24-20: RSI\_XFR\_IMSK0 Register Diagram

Table 24-32: RSI\_XFR\_IMSK0 Register Fields

| Bit No. | Bit Name   | Description/Enumeration                       |
|---------|------------|-----------------------------------------------|
| 21      | RXFIFORDY  | Enable Interrupt for Receive FIFO Available.  |
| 20      | TXFIFORDY  | Enable Interrupt for Transmit FIFO Available. |
| 19      | RXFIFOZERO | Enable Interrupt for Receive FIFO Empty.      |

**Table 24-32:** RSI\_XFR\_IMSK0 Register Fields (Continued)

| Bit No. | Bit Name   | Description/Enumeration                    |
|---------|------------|--------------------------------------------|
| 18      | TXFIFOZERO | Enable Interrupt for Transmit FIFO Empty.  |
| 17      | RXFIFOFULL | Enable Interrupt for Receive FIFO Full.    |
| 16      | TXFIFOFULL | Enable Interrupt for Transmit FIFO Full.   |
| 15      | RXFIFOSTAT | Enable Interrupt for Receive FIFO Status.  |
| 14      | TXFIFOSTAT | Enable Interrupt for Transmit FIFO Status. |
| 13      | RXACT      | Enable Interrupt for Receive Active.       |
| 12      | TXACT      | Enable Interrupt for Transmit Active.      |
| 11      | CMDACT     | Enable Interrupt for Command Active.       |
| 10      | DATBLKEND  | Enable Interrupt for Data Block End.       |
| 9       | STRTBITERR | Enable Interrupt for Start Bit Error.      |
| 8       | DATEND     | Enable Interrupt for Data End.             |
| 7       | CMDSENT    | Enable Interrupt for Command Sent.         |
| 6       | RESPEND    | Enable Interrupt for Command Response End. |
| 5       | RXOVER     | Enable Interrupt for Receive Over run.     |
| 4       | TXUNDR     | Enable Interrupt for Transmit Under run.   |
| 3       | DATTO      | Enable Interrupt for Data Timeout.         |
| 2       | CMDTO      | Enable Interrupt for CMD Timeout.          |
| 1       | DATCRCFAIL | Enable Interrupt for Data CRC Fail.        |
| 0       | CMDCRCFAIL | Enable Interrupt for CMD CRC Fail.         |

## Interrupt 1 Mask Register

### RSI\_XFR\_IMSK1: Interrupt 1 Mask Register - R/W

Reset = 0x0000 0000

**Figure 24-21:** RSI\_XFR\_IMSK1 Register Diagram

# 25 Serial Peripheral Interface (SPI)

The Serial Peripheral Interface is an industry-standard synchronous serial link that supports communication with multiple SPI compatible devices. The baseline SPI peripheral is a synchronous, four-wire interface consisting of two data pins, one device select pin, and a gated clock pin. With the two data pins, it allows for full-duplex operation to other SPI compatible devices. An additional two (optional) data pins are provided to support quad SPI operation. Enhanced modes of operation such as flow control, Fast Mode and dual-I/O mode (DIOM) are also supported. Moreover, a direct memory access (DMA) mode allows for transferring several words with minimal CPU interaction.

The SPI interface includes programmable baud rates, clock phase, and clock polarity. It can operate in a multi-master environment by interfacing with several other devices, acting as either a master device or a slave device. In a multi-master environment, the SPI interface uses open drain outputs to avoid data bus contention.

## SPI Features

The SPI module supports the following features:

- Full-duplex, synchronous serial interface
- Supports 8, 16 and 32-bit word sizes
- Programmable baud rate, clock phase and polarity
- Programmable inter-frame latency
- Flow control
- Support for Fast, DIOM and Quad SPI enhanced modes
- Independent receive and transmit DMA channels
- Burst transfer mode for non-DMA write accesses

## SPI Functional Description

The following sections provide functional descriptions of the SPI:

- [SPI Register List](#)
- [SPI Block Diagram](#)

The SPI is essentially a shift register that serially transmits and receives data bits to/from other SPI devices. During an SPI transfer, data is simultaneously transmitted (shifted out serially) and received (shifted in serially). A serial clock line synchronizes shifting and sampling of the information on the two serial data lines.

During a data transfer, one SPI system acts as the link master which controls the data flow, while the other system acts as the slave, which has data shifted into and out of it by the master. Different devices can take turn being masters, and one master may simultaneously shift data into multiple slaves (broadcast mode). However, only one slave may drive its output to write data back to the master at any given time. This must be enforced in the broadcast mode, where several slaves can be selected to receive data from the master, but only one slave can be enabled to send data back to the master.

SPI supports enhanced modes of operation like Fast Mode, DIOM and Quad-SPI, as well as providing optional flow control. In Fast Mode, received data is sampled on the transmit edge instead of the standard receive edge, thus enabling a full-cycle path for the received data. In DIOM, both MOSI and MISO are configured as input or output pins, and two bits are shifted in or out on each receive or transmit edge. In Quad-SPI mode, SPI\_D3:0 are configured as input or output pins and four bits are shifted in or out on each receive or transmit edge. Flow control can be used by a slower slave to stall a faster master device.

The SPI can be used in a single master as well as multi-master environment. The SPI\_MOSI, SPI\_MISO, and the SPI\_CLK signals are all tied together in both configurations. SPI transmission and reception may be enabled simultaneously or individually, depending on SPI\_RXCTL and SPI\_TXCTL settings. In Broadcast mode, several slaves can be enabled to receive, but only one slaves must be in transmit mode and driving the SPI\_MISO line.

## SPI Register List

The serial peripheral interface SPI provides a full-duplex, synchronous serial interface, which supports both master/slave modes and multi-master environments. The SPI's baud rate and clock phase/polarities are programmable, and it has integrated DMA channels for both transmit and receive data streams. A set of registers govern SPI operations. For more information on SPI functionality, see the SPI register descriptions.

**Table 25-1:** SPI Module Registers

| Name      | Description               |
|-----------|---------------------------|
| SPI_CTL   | Control Register          |
| SPI_RXCTL | Receive Control Register  |
| SPI_TXCTL | Transmit Control Register |
| SPI_CLK   | Clock Rate Register       |

**Table 25-1:** SPI Module Registers (Continued)

## SPI Block Diagram

The figure below illustrates the block diagram of the SPI module. The module is comprised of three primary parts:

- SPI core contains the receive and transmit FIFOs and their associated shift registers.
- Control blocks contain the synchronizer and logic to control the data flow through the data pipelines.
- Register block.

**Figure 25-1:** SPI Controller Block Diagram

## SPI Transfer Protocol

The SPI module implements two channels that are independent of each other. These channels are controlled by their dedicated control registers – SPI\_RX\_CTL and SPI\_TX\_CTL. Except in Dual and Quad modes, both channels may be enabled and used simultaneously.

The SPI protocol supports four different combinations of serial clock phase and polarity. These combinations are selected through the `SPI_CTL.CPOL` and `SPI_CTL.CPHA` bits.

The figures below demonstrate the two basic transfer formats as defined by the `CPHA` bit. Two waveforms are shown for `SPI_CLK`—one for `CPOL = 0` and the other for `CPOL = 1`. The diagrams may be interpreted as master or slave timing diagrams since the `SPI_CLK`, `SPI_MISO` and `SPI_MOSI` pins are directly connected between the master and the slave. The `SPI_MISO` signal is the output from the slave (slave transmission), and the `SPI_MOSI` signal is the output from the master (master transmission). The `SPI_CLK` signal is generated by the master, and the `SPI_SS` signal is the slave device select input to the slave from the master. The diagrams represent an 8-bit transfer (`SPI_CTL.SIZE = 0`) with the MSB first (`SPI_CTL.LSBF = 0`). Any combination of the `SIZE` and `LSBF` bits of `SPI_CTL` is allowed. For example, a 16-bit transfer with the LSB first is another possible configuration.

The clock polarity and the clock phase should be identical for the master device and the slave device involved in the communication link. The transfer format from the master may be changed between transfers to adjust to various requirements of a slave device.

The `SPI_CTL.ASSEL` bit determines if the `SPI_SS` line is controlled by the SPI hardware or by software. When `ASSEL = 1`, the slave select line must be set to the polarity set in the `SPI_CTL.SELST` field between each serial transfer. The actual behavior of `SPI_SS` would also depend on the parameters programmed into the `SPI_DLY` register. This is controlled automatically by the SPI hardware logic. When `ASSEL = 0`, `SPI_SS` may either remain active between successive transfers or be inactive. This must be controlled by the software via manipulation of the `SPI_SSEL` register.

The figures below illustrate the case when `ASSEL = 1` and the `SPI_SS` line is inactive between frames. If `ASSEL = 0`, the `SPI_SS` line may remain active between frames; however, the first bit will only be driven when an active transition of `SPI_CLK` occurs.

**Figure 25-2:** SPI Transfer Protocol for `CPHA=0`

**Figure 25-3:** SPI Transfer Protocol for CPHA=1

## SPI Clock Considerations

The `SPI_CLK` signal is a gated clock that is only active during data transfers, for the duration of the transferred word. In normal mode, the number of active edges is equal to the number of bits to be transmitted or received. In dual-I/O mode it is half of the number of bits to be transmitted or received, and in quad-SPI mode it is one-fourth of the number. The clock rate can be as high as the `SCLK` rate, and both even and odd dividers from `SCLK` are supported. For master devices, the clock rate is determined by the `SPI_CLK` register value, whereas this value is ignored for slave devices.

When the SPI controller is a master, `SPI_CLK` is an output signal. Conversely, when the SPI controller is a slave, `SPI_CLK` is an input signal. Slave devices ignore the SPI clock if the slave select input is driven inactive. The `SPI_CLK` signal is used to shift out and shift in the data driven onto the `SPI_MISO` and `SPI_MOSI` lines. The data is always shifted out on one edge of the clock (the active edge) and sampled on the opposite edge of the clock (the sampling edge). Clock polarity and clock phase relative to data are programmable through the `SPI_CTL` register and define the transfer format.

## Controlling Delay Between Frames

The figure below illustrates SPI timing with `SPI_DLY.LEADX` and `SPI_DLY.LAGX` programming. The `LAGX` controls the timing between the Slave Select (`SPI_SEL`) assertion and the first `SPI_CLK` edge, while `LEADX` controls the timing between the last `SPI_CLK` edge and deassertion of `SPI_SEL`. The lead and lag timing can be extended by 1 `SPI_CLK` duration to ease timing restrictions on the slave device.

**Figure 25-4:** SPI Timing with Lead and Lag Programming (independent of SPI\_CTL.CPHA setting)

The figure below illustrates SPI timing with STOP programming which is used to insert multiples of SPI\_CLK period delays between transfers. The SPI\_SEL line is deasserted for the duration specified in the SPI\_DLY.STOP field, assuming the SPI\_CTL.SELST bit is configured for deassertion between transfers.

If SPI\_DLY.STOP is programmed to zero, the master operates in a *continuous mode*, resulting in immediate start of the second word after the last bit is transferred from the first word. During this mode of operation, the slave select line is continuously asserted.

**Figure 25-5:** SPI Timing with SPI\_DLY.STOP Programming (Independent of SPI\_CTL.CPHA Setting)

When `SPI_DLY.STOP` is zero and initial conditions for a transfer are not met, the interface pauses before the next transfer. During this pause, the state of the slave select pin is determined by the `SPI_CTL.SELST` bit, and the `SPI_DLY.LEAD` and `SPI_DLY.LAG` bits determine the timing between `SPI_CLK` edges and the slave select line.

## SPI Flow Control

In Master mode, the `SPI_RDY` pin acts as an input signal and should be driven by the slave device. `SPI_RDY` can be deasserted by the slave to stop the master from initiating any new transfer. If `SPI_RDY` is deasserted in the middle of a transfer, the current transfer will continue, and the next transfer will not start unless the slave asserts the `SPI_RDY` signal. Whenever the slave deasserts `SPI_RDY` and stalls the master, the SPI controller goes into a waiting state, and the `SPI_STAT.FCS` bit is set. When the slave asserts `SPI_RDY`, the SPI controller resumes operation, and the `SPI_STAT.FCS` bit is cleared.

In Slave mode, the `SPI_RDY` pin acts as an output signal. Flow control can be configured on either the TX channel or the RX channel. This is controlled by the `SPI_CTL.FCCH` bit. If flow control is configured on the TX channel, as the `SPI_TFIFO` status nears the empty condition, `SPI_RDY` is deasserted. If flow control is configured on the RX channel, as the `SPI_RFIFO` status nears the full condition, `SPI_RDY` is deasserted. The FIFO status at which `SPI_RDY` deassertion should take place can be controlled by the `SPI_CTL.FCWM` bits. Note that flow control in Slave mode is purely based on the FIFO status and doesn't depend on the word counters.

**Figure 25-6:** SPI Flow Control Timing in Master Mode.

## SPI Slave Select Operation

If the SPI is in Slave mode,  $\overline{\text{SPI\_SS}}$  acts as the slave select input. When SPI is enabled as a master,  $\overline{\text{SPI\_SS}}$  can serve as an error detection input for the SPI in a multi-master environment. The `SPI_CTL.PSSE` bit enables this feature. When `PSSE = 1`, the  $\overline{\text{SPI\_SS}}$  input is the master mode error input. Otherwise,  $\overline{\text{SPI\_SS}}$  is ignored.

The  $\overline{\text{SPI\_SS}}$  signal is an active-low signal and should be asserted during the transfer by the master. It can be deasserted or remain asserted between transfers. When  $\overline{\text{SPI\_SS}}$  is deasserted, `SPI_CLK` and inputs are ignored, and outputs are three-stated.

The `SPI_SLVSEL.SSEX` bits are used in a multiple-slave SPI environment. For example, if there are eight SPI devices in the system including a processor master, the master processor can support the SPI mode transactions across the other seven devices. This configuration requires only one master processor in this multi-slave environment.

For example, assume that the processor's SPI is the master. `SPI_SSEL1` to `SPI_SSEL7` on the processor can be connected to the slave select pin of each slave device. In this configuration, the `SPI_SLVSEL.SSEX` bits can be used in three ways. In cases 1 and 2, the processor is the master and the seven micro controllers/peripherals with SPI interfaces are slaves. The processor can do one of the following:

1. Transmit to all seven SPI devices at the same time in a broadcast mode. Here, all `SPI_SLVSEL.SSEX` bits are set.
2. Receive and transmit from one SPI device by enabling only one slave SPI device at a time.
3. If all the slaves are also processors, then the requester can receive data from only one processor (enabled by clearing the `SPI_CTL.EMISO` bit in the six other slave processors) at a time and transmit broadcast data to all seven at the same time. This EMISO feature may be available in some other micro controllers. Therefore, it is possible to use the EMISO feature with any other SPI device that includes this functionality.

**Figure 25-7:** Single-Master, Multiple-Slave Configuration

## Beginning and Ending a Non-DMA SPI Transfer

The start and finish of a non-DMA SPI transfer depend on the following settings.

1. Whether the device is configured as a master or a slave
2. The state of the `ASSEL` bit, which selects between hardware and software control over `SSEL`

When `SPI_CTL.CPHA = 0`, the enabled slave select outputs are driven active. However, the `SPI_CLK` signal remains inactive for the first half of the first cycle of `SPI_CLK`. For a slave with `SPI_CTL.CPHA = 0`, the transfer starts as soon as the  $\overline{\text{SPI\_SS}}$  input goes low.

When `SPI_CTL.CPHA = 1`, a transfer starts with the first active edge of `SPI_CLK` for both slave and master devices. For a master device, a transfer is considered finished after it sends the last data and simultaneously receives the last data bit. A transfer for a slave device ends after the last sampling edge of `SPI_CLK`. If `SPI_CTL.ASSEL = 0`, the hardware maintains responsibility for toggling  $\overline{\text{SPI\_SS}}$  between frames. If `SPI_CTL.ASSEL = 1`, software controls the  $\overline{\text{SPI\_SS}}$  line and may keep it active between frames.

The `SPI_STAT.RFE` bit defines when the receive buffer can be read, indicating that `SPI_RFIFO` is not empty. The `SPI_STAT.TFF` bit defines when the transmit buffer can be written, indicating that the `SPI_TFIFO` is not full. The end of a single word transfer occurs when the `SPI_STAT.RFE` bit is cleared, indicating that a new word has just been received and written into the receive FIFO. `SPI_STAT.RFE` remains cleared as long as the receive FIFO has valid data.

To maintain software compatibility with other SPI devices, the `SPI_STAT.SPIF` bit is also available for polling. This bit may have a slightly different behavior from that of other commercially available devices.

In master mode with the `SPI_CTL.ASSEL` bit cleared, software should manually assert the required slave select signal before starting the transaction. After all data has been transferred, software typically releases the slave select line.

When the receive or transmit word counters are enabled in `SPI_TXCTL` or `SPI_RXCTL`, a finish interrupt is generated at the end of the transfer to signal the end of all transfers relating to that transaction.

## **SPI Transmit Operation in Non-DMA Mode**

Transmit operation on non-DMA mode is enabled through the `SPI_TXCTL.TEN` bit. Transmit operation can be enabled independently from receive operation, and the transmit channel can become the initiating channel based on the `SPI_TXCTL.TTI` setting.

Transmit underrun is not possible in this mode, as no new transfer would be initiated unless the transmit FIFO is empty (in the case that `SPI_TXCTL.TTI = 1`). A receive overflow is detected when data from a new frame transfer replaces older data in a full receive FIFO. This can occur if `SPI_TXCTL.TTI = 1` and the receive channel is enabled in a non-initiating capacity.

An SPI transmit interrupt is signalled once the transmit channel has been enabled and the transmit FIFO is not full. The frequency of the interrupt is controlled by the `SPI_TXCTL.TDR` setting.

## **SPI Receive Operation in Non-DMA Mode**

Receive operation on non-DMA mode is enabled through the `SPI_RXCTL.REN` bit. Receive operation can be enabled independently from transmit operation, and the receive channel can become the initiating channel based on the `SPI_RXCTL.RTI` setting.

Receive overflow is not possible in this mode, as no new transfer would be initiated when the receive FIFO is full (in the case of `SPI_RXCTL.RTI = 1`). A transmit underrun can occur (`SPI_TXCTL.TDU`) if no valid data is in the `SPI_TFIFO` register upon initiation of a transfer. This can occur if `SPI_RXCTL.RTI = 1` and the transmit channel is enabled in a non-initiating capacity.

A SPI receive interrupt is signaled once the receive channel has been enabled and there is data waiting to be read. The frequency of the interrupt is controlled by the `SPI_RXCTL.RDR` setting.

## SPI Dual I/O Mode

In Dual I/O mode, the `SPI_MISO` and `SPI_MOSI` pins are configured to operate in the same direction which doubles bandwidth. The order of bits on the pins are determined by the `SPI_CTL.SOSI` bit which, when set, sends the first bit on the `SPI_MOSI` pin and the second bit on the `SPI_MISO` pin. If the `SPI_CTL.SOSI` bit is cleared, the order is reversed. Since Dual I/O mode uses both pins to transmit or receive data, only one channel can be enabled, either transmit or receive. Flow control through the `SPI_RDY` pin is supported. Interrupt generation is unaffected by Dual I/O mode. However, the gap between successive interrupts is reduced, since the individual transfer latency is halved.

Changing to Quad SPI mode should be done when the SPI is in a quiescent state.

**Figure 25-8:** Dual I/O Mode Transfer Protocol for `CPHA=0`, `SOSI=1`, 8-Bit Transfer, `LSBF=0`.

**Figure 25-9:** Dual I/O Mode Transfer Protocol for CPHA=1, SOSI=0, 8-Bit Transfer, LSBF=0.

## SPI Quad I/O Mode

In Quad SPI mode, the SPI\_MISO and SPI\_MOSI pins, in tandem with the SPI\_D2 and SPI\_D3 pins, are configured to operate in the same direction. The order of bits on the pins are determined by the SPI\_CTL.SOSI bit which, when set, sends the first bit on the SPI\_MOSI pin, the second bit on the SPI\_MISO pin, the third bit on the SPI\_D2 pin and the fourth bit on the SPI\_D3 pin. If the SPI\_CTL.SOSI bit is cleared, the order is reversed. Since Quad SPI mode uses all four pins to transmit or receive data, only one channel can be enabled, either Transmit or Receive. Flow control through the SPI\_RDY pin is supported. Interrupt generation is unaffected by Quad SPI mode.

Changing to Quad SPI mode should be done when the SPI is in a quiescent state.

**Figure 25-10:** Quad Mode Timing for CPHA=0, SSI=1, 16-Bit Transfer, LSBF=0.

**NOTE:** Quad SPI 8-bit transfer is not supported in Slave Continuous mode of operation with a SCLK:SPI\_CLK ratio less than 1:2. A minimum of 2 SCLK cycles is required between transfers in 8-bit Quad SPI Slave mode with SCLK:SPI\_CLK ratio less than 1:2.

## SPI Fast Mode

Fast Mode is similar to normal mode of operation when transmitting. When receiving, data is sampled at the next transmit edge allowing a full cycle of timing in the receive direction. This mode is valid in master mode operation only. When the SPI is operating in Fast Mode, the slave should drive the data for one full cycle.

**Figure 25-11:** SPI Transfer Protocol in Fast Mode for SPI\_CTL.CPHA = 0

**Figure 25-12:** SPI Transfer Protocol in Fast Mode for SPI\_CTL.CPHA = 1

## SPI Interrupt Signals

The SPI controller supports three types of interrupt signals, corresponding to data, status, and error conditions.

## SPI Data Interrupts

The SPI peripheral supports two data interrupt channels – receive and transmit. These interrupt signals are multiplexed into the DMA request lines. Since the peripheral interfaces to independent read and write

interfaces with DMA, the read and write data interrupts are independent. When the DMA channel(s) are not being used, the interrupts are routed directly to the system event controller, occupying the same interrupt vector locations as the corresponding DMA channels do.

Each of the data interrupts can be individually controlled by programming the `SPI_RXCTL.RDR` and `SPI_TXCTL.TDR` fields for receive and transmit, respectively. When RX is enabled, the RX interrupt is issued whenever there is data available in the receive data path to be read (according to the `SPI_RXCTL.RDR` setting). When TX is enabled, the TX interrupt is issued whenever the transmit data path can be written to (according to the `SPI_TXCTL.TDR` setting). DMA data interrupts are made compatible with second generation DMA to incorporate urgent data request & transfer finish interrupt apart from usual data request interrupt. Note that transmit interrupts operate independently from the word counter value in `SPI_TWC`.

## SPI Status Interrupts

The SPI controller supports several status interrupts to indicate different conditions of the receiver and transmitter. All status interrupts can be masked. Status interrupts are signaled directly through a single SPI Status IRQ line, which may or may not be combined with the SPI Error IRQ line for a given processor. The following table describes the status interrupts that are available for the SPI controller.

**Table 25-5:** SPI Status Interrupts

| SPI_STAT Bit | Description                                                                                                                                                                                                                                                                                                                                            |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RUWM         | Receive FIFO Urgent Watermark Interrupt. Issued when the level of the RFIFO breaches the watermark set in the <code>SPI_RXCTL.RUWM</code> field. It is cleared when the level of the RFIFO reaches the watermark set in the <code>SPI_RXCTL.RRWM</code> field. If the RX channel is configured in DMA mode, RUWM is multiplexed with the data request. |
| TUWM         | Receive FIFO Urgent Watermark Interrupt. Issued when the level of the TFIFO breaches the watermark set in <code>SPI_TXCTL.TUWM</code> . It is cleared when the level of the TFIFO reaches the watermark set in the <code>SPI_TXCTL.TRWM</code> field. If the TX channel is configured in DMA mode, TUWM is multiplexed with the data request.          |
| TS           | Transmit Start Interrupt. Issued when the start of a transmit burst is detected by loading of <code>SPI_TWC</code> with the contents of <code>SPI_TWCR</code> .                                                                                                                                                                                        |
| RS           | Receive Start Interrupt. Issued when the start of a receive burst is detected by loading of <code>SPI_RWC</code> with the contents of <code>SPI_RWCR</code> .                                                                                                                                                                                          |
| TF           | Transmit Finish Interrupt. Issued when a transmit burst completes ( <code>SPI_TWC</code> decrements to zero).                                                                                                                                                                                                                                          |
| RF           | Receive Finish Interrupt. Issued when a receive burst completes ( <code>SPI_RWC</code> decrements to zero).                                                                                                                                                                                                                                            |

## SPI Error Conditions

The SPI Controller supports interrupts upon several different error conditions. All interrupts are maskable. The individual interrupt indications combine into a single SPI Error IRQ signal, which may be multiplexed on some processors with the aggregated SPI Status IRQ signal. The following table details the possible error indications.

Error conditions and interrupts arise depending on which of the channels (transmit and/or receive) are enabled. If a channel is disabled, all errors relating to it are ignored. When both channels are enabled, errors and interrupts from both channels are enabled.

**Table 25-6:** SPI Error Interrupts

| SPI_STAT Bit | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MF           | Mode Fault. Signalled when another device is also trying to be a master in a multi-master system and drives the SPI_SS input low. This error will be signalled in the Master mode of operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| TUR          | Transmission Error. Signalled when an underflow condition occurs on the transmit channel. This occurs when a new transfer starts but SPI_TFIFO is empty. This error will not occur in Master Transmit Initiating mode since SPI_TFIFO Not Empty is one of the conditions for transfer initiation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ROR          | Reception Error. Signalled when an overflow condition occurs on the receive channel. This occurs when a new data word is received, but the SPI_RFIFO is full. This error condition will not occur in Master Receive Initiating mode since SPI_RFIFO Not Full is one of the conditions for transfer initiation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| TC           | Transmit Collision Error. Signalled when loading data to the transmit shift register happens near the first transmitting edge of SPI_CLK. In Slave mode of operation, the SPI controller is unaware of when the next transfer will start, so loading of data to the transmit shift register may happen just after the transmitting edge. This will result in setup time not being met for the first bit being transmitted, and thus the transmitted data will be corrupted. In SPI_CTL.CPHA = 1 mode, the first SPI_CLK edge is taken as first transmitting edge, whereas if SPI_CTL.CPHA=0 the last SPI_CLK edge of the last transmission (SPI_CTL.SELST=1) or slave select deassertion (SPI_CTL.SELST=0) is taken as the first transmitting edge. This error is signalled only in Slave mode of operation. In Master mode of operation, it is always ensured that loading of data happens before the first transmitting edge of SPI_CLK. |

## SPI Programming Concepts

The following sections provide general programming guidelines and procedures.

## Programming Guidelines

It is acceptable to program `SPI_RX_CTL` and `SPI_TX_CTL` registers after programming `SPI_CTL`, but the initiating mode register and its counter register, if enabled, should be programmed after the non-initiating mode register. For example, if Transmit is the initiating mode and Receive is the non-initiating mode, then `SPI_RX_CTL` and `SPI_RWC` should be programmed before `SPI_TX_CTL` and `SPI_TWC`. If both transmit and receive are to be enabled in initiating mode, `SPI_CTL` should be enabled after programming both `SPI_RX_CTL` and `SPI_TX_CTL`.

These programming guidelines prevent SPI from starting a transfer when SPI registers are still being programmed. Other ways of programming are also allowed as long as commencement of communication is prevented by initiating conditions until all the utilized SPI registers are programmed.

Precautions must be taken to avoid data corruption when changing the SPI module configuration. The configuration must not be changed during a data transfer. Additionally, the clock polarity should only be changed when no slaves are selected. An exception to this is when a SPI communication link consists of a single master and a single slave, `SPI_CTL.ASSEL = 0`, and the slave select input of the slave is permanently tied low. In this case, the slave is always selected, and data corruption can be avoided by enabling the slave only after both the master and slave devices are configured.

The module supports 8, 16 and 32-bit word sizes. To ensure correct operation, both the master and slave must be configured with the same word size.

## SPI Master Operation in Non-DMA Modes

This section describes the operation of the SPI as a master in non-DMA mode.

1. Write to `SPI_SLVSEL`, setting one or more of the SPI Select Enable bits (`SSEx`). This ensures that the desired slaves are properly deselected while the master is configured.
2. The `SPI_RXCTL.RTI` and `SPI_TXCTL.TTI` bits determine the SPI initiating mode. The initiating mode defines the primary transfer channel, and also the initiating condition for the transfer.
3. Write to the `SPI_CLK`, `SPI_CTL`, `SPI_RXCTL` and `SPI_TXCTL` registers, enabling the device as a master and configuring the SPI system by specifying the transfer modes and channels, appropriate word length, transfer format, baud rate, and other control information.

*ADDITIONAL INFORMATION:* If `SPI_RXCTL.RTI` is enabled and `SPI_TXCTL.TTI` is not, write to the `SPI_RXCTL` after writing into `SPI_CTL`, `SPI_TXCTL` and `SPI_TFIFO` to prevent a transmit underrun for the first transfer.

4. If `SPI_CTL.ASSEL = 0`, the user activates the desired slaves by clearing one or more of the `SPI_SLVSEL` flag bits. Otherwise, the SPI hardware takes care of slave activation.
5. The SPI controller then generates the programmed clock pulses on `SPI_CLK` and simultaneously shifts data out of `SPI_MOSI` while shifting data in from `SPI_MISO`. Before a shift, the shift register is loaded

with the contents of the SPI\_TFIFO register. At the end of the transfer, the contents of the shift register are loaded into SPI\_RFIFO.

6. Whenever the initiating conditions are satisfied, the SPI continues to send and receive words. If the transmit buffer remains empty or the receive buffer remains full, the device operates according to the states of the SPI\_TXCTL.TDU and SPI\_RXCTL.RDO bits.
7. It is possible to program a secondary channel in addition to the initiating channel. This feature allows the user to utilize the unused channel resources for receives or transmits simultaneously with the initiating channel.

## **SPI Slave Operation in Non-DMA Modes**

When a device is enabled as a slave in a non-DMA mode, the start of a transfer is triggered by a transition of the  $\overline{\text{SPI\_SS}}$  select signal to the active state (low), or by the first active edge of SPI\_CLK, depending on the state of SPI\_CTL.CPHA. The interface operates in the following manner:

1. The core writes to the SPI\_CTL, SPI\_RXCTL and SPI\_TXCTL registers to define the mode of the serial link to be the same as the mode setup in the SPI master.
2. To prepare for the data transfer, the core writes data to be transmitted into SPI\_TFIFO.
3. Once the  $\overline{\text{SPI\_SS}}$  falling edge is detected, the slave starts sending data on active SPI\_CLK edges and sampling data on inactive SPI\_CLK edges.
4. Reception/transmission continues until  $\overline{\text{SPI\_SS}}$  is released or until the slave has received the proper number of clock cycles.
5. The slave device continues to receive/transmit with each new falling edge transition on  $\overline{\text{SPI\_SS}}$  and/or active SPI\_CLK edge. If the transmit buffer remains empty or the receive buffer remains full, the device operates according to the states of the SPI\_TXCTL.TDU and SPI\_RXCTL.RDO bits.

## **Configuring SPI DMA Master Mode**

The SPI interface supports a write DMA channel and a read DMA channel. These may be used individually or in a lock-step manner in duplex mode (SPI\_TXCTL.TTI= SPI\_RXCTL.RTI=1)

1. Write to the appropriate DMA registers to enable the SPI DMA Channel and to configure the necessary work units, access direction, word count, and so on.
2. Write to the SPI\_SLVSEL register, setting one or more of the SPI flag select bits.
3. Write to the SPI\_CLK and SPI\_CTL registers, enabling the device as a master and configuring the SPI system by specifying the appropriate word length, transfer format, baud rate, etc.
4. Write to SPI\_RXCTL to configure SPI Master Receive mode, and/or write to SPI\_TXCTL to configure SPI Master Transmit mode.

5. Finally, write to `SPI_RXCTL.REN` to enable the receive channel, and/or write to `SPI_TXCTL.TEN` to enable the transmit channel.
6. If `SPI_RXCTL.RTI` is enabled, a receive transfer is initiated upon enabling `SPI_CTL.EN`. If the Receive Word Counter is enabled (`SPI_RXCTL.RWCEN = 1`), then `SPI_RWC` must be non-zero for a transfer to initiate.

*ADDITIONAL INFORMATION:* If enabling both RX and TX DMA channels, but not enabling `SPI_TXCTL.TTI`, write to `SPI_RXCTL` after writing `SPI_CTL` and `SPI_TXCTL`, so that a transmit underrun can be prevented for the first transfer. Subsequent transfers are initiated as the SPI reads data from the RX shift register and writes to the SPI Receive FIFO. The SPI then requests a DMA write to memory. Upon a DMA grant, the DMA engine reads a word from the SPI Receive FIFO and writes to memory. New requests continue to be initiated as long as the receive FIFO does not fill up, provided that `SPI_RWC` does not become zero while `SPI_RXCTL.RWCEN = 1`.

7. If `SPI_TXCTL.TTI` is enabled, the SPI controller requests DMA reads from memory as long as there is space for more data in the transmit pipe. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO. As long as transmit data is available in the FIFO, and the `SPI_TWC` register is non-zero if `SPI_TXCTL.TWCEN = 1`, the SPI continues to initiate transfers until disabled.
8. If both `SPI_TXCTL.TTI` and `SPI_RXCTL.RTI` are enabled, the SPI controller requests a DMA read from memory as long as there is space for more data in the transmit pipe and the number of words written into the SPI is less than `SPI_TWC` if `SPI_TXCTL.TWCEN = 1`. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO.

*ADDITIONAL INFORMATION:* As the SPI writes data from the transmit FIFO into the transmit shift Register, it initiates a transfer on the SPI link.

- a) Data received from the transfer is moved from the SPI receive shift register to the receive FIFO.
- b) The SPI controller requests a DMA write to memory.
- c) Upon a DMA grant, the DMA engine reads a word from the receive FIFO and writes to memory. Transfer will continue to be initiated as long as both receives and transmits can accommodate new data
9. If the receive pipe fills up due to unavailability of DMA grants, the transmit pipe will stall until the pipe is drained. If the transmit pipe fills up, the SPI will stop requesting for DMA writes. If the value in `SPI_RWC` expires, further write requests to DMA will stop. However, data already written into the transmit FIFO will transmit, and read requests to DMA will continue until the receive data is read from the receive FIFO.
10. The SPI then generates the programmed clock pulses on `SPI_CLK` and simultaneously shifts data out of `SPI_MOSI` while shifting data in from `SPI_MISO`. For receive transfers, the value in the shift register is loaded into the `SPI_RFIFO` register at the end of the transfer. For transmit transfers, the value in the `SPI_TFIFO` register is loaded into the shift register at the start of the transfer.

## Configuring SPI DMA Slave Mode Operation

When enabled as a slave with the DMA engine configured to transmit or receive data, the start of a transfer is triggered by a transition of the `SPI_SS` signal to the active-low state or by the first active edge of `SPI_CLK`, depending on the state of `SPI_CTL.CPHA`. The following steps illustrate the SPI receive or transmit DMA sequence in an SPI slave (in response to a master command). The SPI supports a receive DMA channel and a transmit DMA channel.

1. Write to the appropriate DMA registers to enable the SPI DMA channel and configure the necessary work units, access direction, word count, and so on.
2. Write to the `SPI_CTL`, `SPI_RXCTL` and `SPI_TXCTL` registers to define the mode of the serial link to be the same as the mode configured in the SPI master.
3. If the receive channel is enabled (`SPI_RXCTL.REN` is asserted), the following actions occur:
  - a. Once the slave select input is active, the slave starts receiving and transmitting data on active `SPI_CLK` edges.
  - b. The value in the shift register is loaded into the `SPI_RFIFO` register at the end of the transfer.
  - c. Once `SPI_RFIFO` has valid data, it requests a DMA write to memory.
  - d. Upon a DMA grant, the DMA engine reads a word from the receive FIFO and writes to memory.
  - e. As long as there is data in the receive FIFO, the SPI slave continues to request a DMA write to memory. The DMA engine continues to read a word from the FIFO and writes to memory until the `SPI_RWC` counts to zero. The SPI slave continues receiving words on active `SPI_CLK` edges as long as the `SPI_SS` input is active.
  - f. If the data collected in the receive pipe breaches the level set according to the `SPI_CTL.FCWM` field, and the DMA engine is unable to keep up with the receive rate, the slave may de-assert the `SPI_RDY` signal, throttling the master. The signal is deasserted as the DMA drains the receive FIFO. Alternatively, the `SPI_RXCTL.RDO` bit can decide if the incoming data is discarded or overwritten into the receive FIFO (when `SPI_CTL.FCEN` is inactive).
4. If the transmit channel is enabled (`SPI_TXCTL.TEN` is asserted), the following actions occur:
  - a. The SPI requests a DMA read from memory.
  - b. Upon a DMA grant, the DMA engine reads a word from memory and writes to the transmit FIFO.
  - c. The SPI then reads DMA data from the transmit FIFO and writes to the transmit shift register, awaiting the start of the next transfer.
  - d. Once the slave select input is active, the slave starts receiving and transmitting data on active `SPI_CLK` edges.
  - e. As long as there is room in the transmit FIFO, the SPI slave continues to request a DMA read from memory. The DMA engine continues to read a word from memory and write to the transmit FIFO.

until the SPI\_TWC register value counts down to 0. The SPI slave continues transmitting words on active SPI\_CLK edges as long as the  $\overline{\text{SPI\_SS}}$  input is active.

- f. If the number of outstanding data entries waiting for transmission in the transmit pipe breaches the level set according to the SPI\_CTL.FCWM field and the DMA is unable to keep up with the transmit rate, the slave may deassert the SPI\_RDY signal, throttling the master. The signal is deasserted as the DMA fills the transmit FIFO. Alternately the SPI\_TXCTL.TDU bit decides the state of the transmit data (when SPI\_CTL.FCEN is deasserted).
5. If both receive and transmit channels are enabled, the following actions occur after the actions stated above for each channel. Transfers will continue as long as both receives and transmits can accommodate new data.
    - a. If the receive pipe fills up due to unavailability of DMA grant, the SPI interface will stall the master by asserting the SPI\_RDY pin. This signal is deasserted as the DMA drains the receive FIFO. Alternately, the SPI\_RXCTL.RDO bit decides if the incoming data is discarded or overwritten into the receive FIFO (when SPI\_CTL.FCEN is deasserted).
    - b. If the transmit pipe fills up, the SPI will stop requesting for DMA writes until the pipe clears.
    - c. If there is an underflow problem in the transmit pipe, the slave will stall the master by deasserting SPI\_RDY while DMA fills the transmit FIFO. Alternately, the SPI\_TXCTL.TDU bit decides the state of the transmit data (when SPI\_CTL.FCEN is deasserted).

## SPI Register Descriptions

Serial Peripheral Interface (SPI) contains the following registers.

**Table 25-7:** SPI Module Registers

| Name       | Description                         |
|------------|-------------------------------------|
| SPI_CTL    | Control Register                    |
| SPI_RXCTL  | Receive Control Register            |
| SPI_TXCTL  | Transmit Control Register           |
| SPI_CLK    | Clock Rate Register                 |
| SPI_DLY    | Delay Register                      |
| SPI_SLVSEL | Slave Select Register               |
| SPI_RWC    | Received Word Count Register        |
| SPI_RWCR   | Received Word Count Reload Register |

**Table 25-7:** SPI Module Registers (Continued)

| Name         | Description                            |
|--------------|----------------------------------------|
| SPI_TWC      | Transmitted Word Count Register        |
| SPI_TWCR     | Transmitted Word Count Reload Register |
| SPI_IMSK     | Interrupt Mask Register                |
| SPI_IMSK_CLR | Interrupt Mask Clear Register          |
| SPI_IMSK_SET | Interrupt Mask Set Register            |
| SPI_STAT     | Status Register                        |
| SPI_ILAT     | Masked Interrupt Condition Register    |
| SPI_ILAT_CLR | Masked Interrupt Clear Register        |
| SPI_RFIFO    | Receive FIFO Data Register             |
| SPI_TFIFO    | Transmit FIFO Data Register            |

## Control Register

The SPI\_CTL register enables the SPI and configures settings for operating modes, communication protocols, and buffer operations.

### SPI\_CTL: Control Register - R/W

Reset = 0x0000 0050

**Figure 25-13:** SPI\_CTL Register Diagram

**Table 25-8:** SPI\_CTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 22      | SOSI     | <p>Start on MOSI.</p> <p>The SPI_CTL.SOSI bit is valid only when SPI_CTL.MIOM is enabled for either DIOM or QIOM, and this bit selects the starting pin and the bit placement on pins for these modes.</p> <p>In DIOM, enabling SPI_CTL.SOSI sends bit 1 on the SPI_MOSI pin and sends bit 2 on the SPI_MISO pin. Disabling SPI_CTL.SOSI reverses this order.</p> <p>In QIOM, enabling SPI_CTL.SOSI sends bit 1 on the SPI_MOSI pin, sends bit 2 on the SPI_MISO pin, sends bit 3 on SPI_D2 pin, and sends bit 4 on the SPI_D3 pin. Disabling SPI_CTL.SOSI reverses this order.</p> |

SPI transmit operations in fast mode are the same as normal mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                      |
|         |          | 0 Disable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|         |          | 1 Enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Table 25-8:** SPI\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                     |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 17:16   | FCWM     | Flow Control Watermark.<br>The SPI_CTL.FCWM bits select the watermark level of the transmit channel (SPI_TFIFO buffer) or receive channel (SPI_RFIFO buffer) that triggers flow control operation. These bits are applicable only when the SPI is a slave (SPI_CTL.MSTR = 0) and flow control is enabled (SPI_CTL.FCEN = 1). When the watermark condition is met, the SPI slave de-asserts the SPI_RDY pin. |
|         |          | 0      TFIFO empty or RFIFO full                                                                                                                                                                                                                                                                                                                                                                            |
|         |          | 1      TFIFO 75% or more empty, or RFIFO full                                                                                                                                                                                                                                                                                                                                                               |
|         |          | 2      TFIFO 50% or more empty, or RFIFO full                                                                                                                                                                                                                                                                                                                                                               |
|         |          | 3      Reserved                                                                                                                                                                                                                                                                                                                                                                                             |
| 15      | FCPL     | Flow Control Polarity.<br>The SPI_CTL.FCPL bit selects flow control polarity for the SPI_RDY pin when flow control is enabled. When the SPI_RDY pin is active, the SPI is indicating it's ready for data transfer.                                                                                                                                                                                          |
|         |          | 0      Active-low RDY                                                                                                                                                                                                                                                                                                                                                                                       |
|         |          | 1      Active-high RDY                                                                                                                                                                                                                                                                                                                                                                                      |
| 14      | FCCH     | Flow Control Channel Selection.<br>The SPI_CTL.FCCH bit selects whether the SPI applies flow control to the transmit channel (SPI_TFIFO buffer) or receive channel (SPI_RFIFO buffer). This bit is applicable only when the SPI is a slave and flow control is enabled.                                                                                                                                     |
|         |          | 0      Flow control on RX buffer                                                                                                                                                                                                                                                                                                                                                                            |
|         |          | 1      Flow control on TX buffer                                                                                                                                                                                                                                                                                                                                                                            |

**Table 25-8:** SPI\_CTL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                          |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 13      | FCEN     | Flow Control Enable.<br>The SPI_CTL.FCEN bit enables SPI flow control operation, which permits slow slave devices to interface with fast master devices. This bit controls operation of the SPI_RDY pin. Note that options for flow control operation are available using the SPI_CTL.FCCH, SPI_CTL.FCPL, and SPI_CTL.FCWM bits. |
|         |          | 0      Disable                                                                                                                                                                                                                                                                                                                   |
|         |          | 1      Enable                                                                                                                                                                                                                                                                                                                    |
| 12      | LSBF     | Least Significant Bit First.<br>The SPI_CTL.LSBF bit selects whether the SPI transmits/receives data as LSB first (little endian) or MSB first (big endian). This bit may only be changed when the SPI is disabled.                                                                                                              |
|         |          | 0      MSB sent/received first (big endian)                                                                                                                                                                                                                                                                                      |
|         |          | 1      LSB sent/received first (little endian)                                                                                                                                                                                                                                                                                   |
| 10:9    | SIZE     | Word Transfer Size.<br>The SPI_CTL.SIZE bits select the SPI transfer word size as 8, 16 or 32 bits. To ensure correct operation, both the master and slave must be configured with the same word size. This bit may only be changed when the SPI is disabled (SPI_CTL.EN = 0).                                                   |

| 7       | SELST    | Slave Select Polarity Between Transfers.<br>The SPI_CTL.SELST bit selects the state (polarity) for the $\overline{\text{SPI\_SELN}}$ pin in-between SPI transfers when the SPI is a master and slave select assertion is enabled (SPI_CTL.ASSEL =1).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|         |          | 0 De-assert slave select (high)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|         |          | 1 Assert slave select (low)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 6       | ASSEL    | Slave Select Pin Control.<br>The SPI_CTL.ASSEL bit selects whether the SPI hardware sets the $\overline{\text{SPI\_SELN}}$ pin output value (ignoring the slave select SPI_SLVSEL.SSEL1 - SPI_SLVSEL.SSEL7 bits) or whether software control of the slave select bits set the $\overline{\text{SPI\_SELN}}$ pin output value. This feature is applicable only when the SPI is a master.<br>When hardware control is enabled, the $\overline{\text{SPI\_SELN}}$ pin output is asserted during the transfers, and the pin polarity between transfers is selected by the SPI_CTL.SELST bit.<br>When software control is enabled, the $\overline{\text{SPI\_SELN}}$ pin output value is set through software control of the slave select bits, and as such, the pin may either remain asserted (low) or be deasserted between transfers. |
|         |          | 0 Software Slave Select Control                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|         |          | 1 Hardware Slave Select Control                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 5       | CPOL     | Clock Polarity.<br>The SPI_CTL.CPOL bit selects whether the SPI uses an active-low or active-high signal for the SPI clock (SPI_CLK). This bit works with the SPI_CTL.CPHA bit to select combinations of clock phase and polarity for the SPI_CLK pin. This bit may only be changed when the SPI is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| 4       | CPHA     | Clock Phase.<br>The SPI_CTL.CPHA bit selects whether the SPI starts toggling the signal for the SPI clock (SPI_CLK) from the start of the first data bit or from the middle of the first data bit. The SPI_CTL.CPHA bit works with the SPI_CTL.CPOL bit to select combinations of clock phase and polarity for the SPI_CLK pin. This bit may only be changed when the SPI is disabled.                                                                                                                                                                                                                                                                                                                                                                    |                             |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | SPI CLK toggles from middle |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | SPI CLK toggles from start  |
| 3       | ODM      | Open Drain Mode.<br>The SPI_CTL.ODM bit configures the data output pins (SPI_MOSI and SPI_MISO) to behave as open drain outputs, which prevents contention and possible damage to pin drivers in multi-master or multi-slave SPI systems.<br>When SPI_CTL.ODM is enabled and the SPI is a master, the SPI three-states the SPI_MOSI pin when the data driven out on MOSI is a logic-high. The SPI does not three-state the SPI_MOSI pin when the driven data is a logic-low.<br>When SPI_CTL.ODM is enabled and the SPI is a slave, the SPI three-states the SPI_MISO pin when the data driven out on SPI_MISO is a logic-high.<br>Note that an external pull-up resistor is required on both the SPI_MOSI and SPI_MISO pins when SPI_CTL.ODM is enabled. |                             |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Disable                     |
|         |          | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Enable                      |
| 2       | PSSE     | Protected Slave Select Enable.<br>The SPI_CTL.PSSE bit enables the $\overline{\text{SPI\_SS}}$ pin to provide error detection input in a multi-master environment when the SPI is in master mode. If some other device in the system asserts the $\overline{\text{SPI\_SS}}$ pin while SPI is enabled as master (and SPI_CTL.PSSE is enabled), this condition causes a mode fault error.                                                                                                                                                                                                                                                                                                                                                                  |                             |
|         |          | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Disable                     |

## Receive Control Register

The SPI\_RXCTL register enables the SPI receive channel, initiates receive transfers, and configures SPI\_RFIFO buffer watermark settings.

### SPI\_RXCTL: Receive Control Register - R/W

Reset = 0x0000 0000

**Figure 25-14:** SPI\_RXCTL Register Diagram

**Table 25-9:** SPI\_RXCTL Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 18:16   | RUWM     | Receive FIFO Urgent Watermark.<br>The SPI_RXCTL.RUWM bits select the receive FIFO (SPI_RFIFO) watermark level for urgent data bus requests. The SPI also uses this watermark level for generation of the SPI_ILAT.RUWM interrupt. When an urgent SPI_RFIFO watermark is enabled with SPI_RXCTL.RUWM, the SPI_RXCTL.RRWM selection is used as the de-assertion condition for any SPI_ILAT.RUWM interrupts that are latched. |
|         |          | 0 Disabled                                                                                                                                                                                                                                                                                                                                                                                                                 |

Transmit Control Register

The SPI\_TXCTL register enables the SPI transmit channel, initiates transmit transfers, and configures SPI\_TFIFO buffer watermark settings.

SPI\_TXCTL: Transmit Control Register - R/W

Reset = 0x0000 0000

## Clock Rate Register

The SPI\_CLK register selects the baud rate for SPI data transfers, relating this rate to the SPI serial clock (SCK) and the system clock (SCLK).

**SPI\_CLK: Clock Rate Register - R/W**

Reset = 0x0000 0000

**Figure 25-16:** SPI\_CLK Register Diagram

Table 25-11: SPI\_CLK Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                       |
|---------|----------|-------------------------------------------------------------------------------------------------------------------------------|
| 15:0    | BAUD     | Baud Rate.<br>The SPI_CLK.BAUD bits set the SPI baud rate according to the formula:<br>$BAUD = (SCLK / \text{SPI Clock}) - 1$ |

Delay Register

The SPI\_DLY register selects a transfer delay and the lead/lag timing between slave select signals and SPI clock edge assertion/de-assertion.

SPI\_DLY: Delay Register - R/W

Reset = 0x0000 0301

Figure 25-17: SPI\_DLY Register Diagram

Table 25-12: SPI\_DLY Register Fields

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                        |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9       | LAGX     | Extended SPI Clock Lag Control.<br>The SPI_DLY.LAGX bit enables insertion of a 1-SPI_CLK cycle lag (extend lag) in the timing between the slave select ( <u>SPI_SELN</u> ) assertion and first SPI Clock edge. |
|         |          | 0 Disable                                                                                                                                                                                                      |

| 8       | LEADX    | Extended SPI Clock Lead Control.<br>The SPI_DLY.LEADX bit enables insertion of a 1-SPI_CLK cycle lead (extend lead) in the timing between the slave select ( $\overline{\text{SPI\_SELN}}$ ) de-assertion and last SPI Clock edge.                                                                                                                                                                                          |
|         |          | 0                      Disable                                                                                                                                                                                                                                                                                                                                                                                              |
|         |          | 1                      Enable                                                                                                                                                                                                                                                                                                                                                                                               |
| 7:0     | STOP     | Transfer delay time in multiples of SPI clock period.<br>The SPI_DLY.STOP bits select a delay (number of stop bits in multiples of SPI Clock duration) at the end of each SPI transfer. The default delay is the minimum value required to comply with the SPI protocol (1-bit duration). The SPI_DLY.STOP bits may be programmed with smaller delay values, resulting in continuous operation (for example, stop bits =0). |

## Slave Select Register

The SPI\_SLVSEL register enables the  $\overline{\text{SPI\_SELN}}$  pins for input and indicates the state (high or low) of these pins when enabled.

SPI\_SLVSEL: Slave Select Register - R/W

Reset = 0x0000 fe00

**Table 25-13:** SPI\_SLVSEL Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7       | SSE7     | Slave Select 7 Enable.<br>The SPI_SLVSEL.SSE7 bit enables the related $\overline{\text{SPI\_SELN}}$ pin for input. If disabled, the SPI three-states the related $\overline{\text{SPI\_SELN}}$ pin. When the SPI is a slave, the master selecting the slave asserts the input during the transfer. The input may be de-asserted or remain asserted between transfers. While the input is de-asserted, the SPI ignores SPI Clock, ignores inputs, and three-states outputs. When the SPI is a master and the SPI_CTL.PSSE bit is enabled, the input serves as an error detection input in a multi-master environment. |
|         |          | 0      Disable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|         |          | 1      Enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Received Word Count Register

The SPI\_RWC register holds a count of the number of words remaining to be received by the SPI. To start the decrement of the word count in SPI\_RWC, enable the receive word counter (SPI\_RXCTL.RWCEN = 1). The SPI uses the word count to control the duration of transfers and to signal the completion of a burst of transfers with the receive finish interrupt (SPI\_ILAT.RF). In DMA mode, the SPI uses the SPI\_RWC to ensure that the number of frames received during a DMA transfer is equal to the number of words programmed in the DMA channel controller. The values programmed into the SPI\_RWC registers should match the word count in the DMA configuration. The SPI\_RWC maintains the number of frames to be received in a transfer. The SPI\_RWC should only be changed when the counter is disabled.

| Bit No. | Bit Name | Description/Enumeration                                                              |
|---------|----------|--------------------------------------------------------------------------------------|
| 15:0    | VALUE    | Received Word Count.<br>The SPI_RWC.VALUE bits hold the receive transfer word count. |

Received Word Count Reload Register

The SPI\_RWCR register holds the receive word count value that the SPI loads into the SPI\_RWC register when the transfer count decrements to zero. To prevent the SPI from reloading the counter, use zero for the reload count value. The SPI\_RWCR should only be changed when the counter is disabled.

SPI\_RWCR: Received Word Count Reload Register - R/W

Reset = 0x0000 0000

|---------|----------|-----------------------------------------------------------------------------------------------------------|
| 15:0    | VALUE    | Received Word Count Reload.<br>The SPI_RWCR.VALUE bits hold the receive transfer word count reload value. |

## Transmitted Word Count Register

The SPI\_TWC register holds a count of the number of words remaining to be transmitted by the SPI. To start the decrement of the word count in SPI\_TWC, enable the transmit word counter (SPI\_TXCTL.TWCEN =1). The SPI uses the word count to control the duration of transfers and to signal the completion of a burst of transfers with the transmit finish interrupt. In DMA mode, the SPI uses the SPI\_TWC to ensure that the number of frames transmitted during a DMA transfer is equal to the number of words programmed in the DMA channel controller. The values programmed into the SPI\_TWC registers should match the word count in the DMA configuration. The SPI\_TWC maintains the number of frames to be transmitted in a transfer. The SPI\_TWC should only be changed when the counter is disabled.

### SPI\_TWC: Transmitted Word Count Register - R/W

Reset = 0x0000 0000

| Bit No. | Bit Name | Description/Enumeration                                                                                       |
|---------|----------|---------------------------------------------------------------------------------------------------------------|
| 15:0    | VALUE    | Transmitted Word Count Reload.<br>The SPI_TWCR.VALUE bits hold the transmit transfer word count reload value. |

Interrupt Mask Register

The SPI\_IMSK register unmask (enables) or mask (disables) SPI interrupts. When a condition is indicated by a bit in the SPI\_STAT register and the corresponding interrupt is unmasked in SPI\_IMSK, the SPI latches the interrupt's bit in the SPI\_ILAT register, queuing the interrupt for service.

**SPI\_IMSK: Interrupt Mask Register - R/WE**

Reset = 0x0000 0000

**Figure 25-23:** SPI\_IMSK Register Diagram

**Table 25-18:** SPI\_IMSK Register Fields

| Bit No. | Bit Name | Description/Enumeration          |
|---------|----------|----------------------------------|
| 11      | TF       | Transmit Finish Interrupt Mask.  |
|         |          | 0      Disable (mask) interrupt  |
|         |          | 1      Enable (unmask) interrupt |

## Interrupt Mask Clear Register

The SPI\_IMSK\_CLR register permits clearing individual mask bits in the SPI\_IMSK register without affecting other bits in the register. Use write-1-to-clear on a bit in SPI\_IMSK\_CLR to clear the corresponding bit in the SPI\_IMSK register.

### SPI\_IMSK\_CLR: Interrupt Mask Clear Register - R/W

Reset = 0x0000 0000

Figure 25-24: SPI\_IMSK\_CLR Register Diagram

Table 25-19: SPI\_IMSK\_CLR Register Fields

| Bit No. | Bit Name | Description/Enumeration                  |
|---------|----------|------------------------------------------|
| 11      | TF       | Clear Transmit Finish Interrupt Mask.    |
| 10      | RF       | Clear Receive Finish Interrupt Mask.     |
| 9       | TS       | Clear Transmit Start Interrupt Mask.     |
| 8       | RS       | Clear Receive Start Interrupt Mask.      |
| 7       | MF       | Clear Mode Fault Interrupt Mask.         |
| 6       | TC       | Clear Transmit Collision Interrupt Mask. |
| 5       | TUR      | Clear Transmit Under-run Interrupt Mask. |
| 4       | ROR      | Clear Receive Overrun Interrupt Mask.    |

Table 25-19: SPI\_IMSK\_CLR Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                         |
|---------|----------|-------------------------------------------------|
| 2       | TUWM     | Clear Transmit Urgent Watermark Interrupt Mask. |
| 1       | RUWM     | Clear Receive Urgent Watermark Interrupt Mask.  |

Interrupt Mask Set Register

The SPI\_IMSK\_SET register permits setting individual mask bits in the SPI\_IMSK register without affecting other bits in the register. Use write-1-to-set on a bit in SPI\_IMSK\_SET to set the corresponding bit in the SPI\_IMSK register.

SPI\_IMSK\_SET: Interrupt Mask Set Register - R/W

Reset = 0x0000 0000

Figure 25-25: SPI\_IMSK\_SET Register Diagram

Table 25-20: SPI\_IMSK\_SET Register Fields

| Bit No. | Bit Name | Description/Enumeration             |
|---------|----------|-------------------------------------|
| 11      | TF       | Set Transmit Finish Interrupt Mask. |
| 10      | RF       | Set Receive Finish Interrupt Mask.  |
| 9       | TS       | Set Transmit Start Interrupt Mask.  |

**Table 25-20:** SPI\_IMSK\_SET Register Fields (Continued)

| Bit No. | Bit Name | Description/Enumeration                       |
|---------|----------|-----------------------------------------------|
| 8       | RS       | Set Receive Start Interrupt Mask.             |
| 7       | MF       | Set Mode Fault Interrupt Mask.                |
| 6       | TC       | Set Transmit Collision Interrupt Mask.        |
| 5       | TUR      | Set Transmit Under-run Interrupt Mask.        |
| 4       | ROR      | Set Receive Overrun Interrupt Mask.           |
| 2       | TUWM     | Set Transmit Urgent Watermark Interrupt Mask. |
| 1       | RUWM     | Set Receive Urgent Watermark Interrupt Mask.  |

## Status Register

The SPI\_STAT register indicates SPI status including FIFO status, error conditions, and interrupt conditions. When an interrupt condition from this register is unmasked (enabled) by the corresponding bit in the SPI\_IMSK register, the interrupt is latched into the corresponding bit in the SPI\_ILAT register.

SPI\_STAT: Status Register - R/W

Reset = 0x0140 0001

## Masked Interrupt Condition Register

The SPI\_ILAT register latches interrupts, queuing the interrupts for service. When a condition is indicated by a bit in the SPI\_STAT register and the corresponding interrupt is unmasked in SPI\_IMSK, the SPI latches the interrupt's bit in SPI\_ILAT.

**SPI\_ILAT: Masked Interrupt Condition Register - R/WE**

Reset = 0x0000 0000

**Figure 25-27: SPI\_ILAT Register Diagram**

**Table 25-22: SPI\_ILAT Register Fields**

| Bit No. | Bit Name | Description/Enumeration          |
|---------|----------|----------------------------------|
| 11      | TF       | Transmit Finish Interrupt Latch. |

## Masked Interrupt Clear Register

The SPI\_ILAT\_CLR register permits clearing individual mask bits in the SPI\_ILAT register without affecting other bits in the register. Use write-1-to-clear on a bit in SPI\_ILAT\_CLR to clear the corresponding bit in the SPI\_ILAT register.

Receive FIFO Data Register

The SPI\_RFIFO register has an interface to the receive shift register in the SPI and has an interface to the processor's data buses. The top level of the buffer is visible to programs as the 32-bit SPI\_RFIFO register, but the size (number of word locations) of the receive FIFO is actually flexible with transfer word size. The size of the receive FIFO is 8 if word size is 8-bit, or the size is 4 if word size is 16-bit, or the size is 2 if word size is 32-bit.

Both masters and slaves may stop or stall receive transfers based on FIFO status. When the receive FIFO is full, the SPI master stops initiating new transfers on the SPI if SPI\_RXCTL.RTI is enabled. A slave may stall the SPI interface when the content of the FIFO crosses the selected watermark. If data reception continues after SPI\_RFIFO is full, the data in the receive FIFO is invalid, and the SPI indicates this condition with receive overrun (SPI\_STAT.ROR). This condition is possible when SPI\_RXCTL.RTI =0 and SPI\_RXCTL.REN =1 for a master, or for a slave that does not exercise flow control.

Note that the receive FIFO is reset (cleared) when the SPI is disabled after being enabled.

## Transmit FIFO Data Register

The `SPI_TFIFO` register has an interface to the transmit shift register in the SPI and has an interface to the processor's data buses. The top level of the buffer is visible to programs as the 32-bit `SPI_TFIFO` register, but the size (number of word locations) of the transmit FIFO is actually flexible with transfer word size. The size of the transmit FIFO is 8 if word size is 8-bit, or the size is 4 if word size is 16-bit, or the size is 2 if word size is 32-bit.

Both masters and slaves may stop or stall transmit transfers based on FIFO status. When the transmit FIFO is empty, the SPI master stops initiating new transfers on the SPI if `SPI_TXCTL.TTI` is enabled. A slave may stall the SPI interface when the content of the FIFO crosses the selected watermark. If data transmit requests continue after `SPI_TFIFO` is empty, the data sent from the transmit FIFO is invalid, and the SPI indicates this condition with transmit underrun (`SPI_STAT.TUR`). This condition is possible when `SPI_TXCTL.TTI = 0` and `SPI_TXCTL.TEN = 1` for a master, or for a slave that does not exercise flow control.

Note that the transmit FIFO is reset (cleared) when the SPI is disabled after being enabled.

## 26 Serial Port (SPORT)

Unlike the SPI interface, which has been designed for SPI-compatible communication only, the serial ports (SPORTs) support a variety of serial data communication protocols. In addition, the SPORTs provide a glueless hardware interface to many industry-standard data converters and codecs. With support for high data rates and dual half-duplex data paths, the SPORT interface is a perfect choice for direct serial interconnection between two or more processors in a multiprocessor system. Many processors provide compatible serial interfaces, including DSPs from Analog Devices and other manufacturers.

The SPORT top module comprises of two half SPORTs with identical functionality. Each SPORT half can be independently configured as either a transmitter or receiver and can be coupled with the other HSPORT within the same SPORT. Further, each SPORT half provides two synchronous half-duplex data lines to double the total supported data streams.

Each SPORT half has the same capabilities and is programmed in the same way. The interface specifications of each SPORT half are shown in the following table.

**Table 26-1:** SPORT Specifications

| Feature                                   | Availability                                                                                |
|-------------------------------------------|---------------------------------------------------------------------------------------------|
| Connectivity                              |                                                                                             |
| Multiplexed Pinout                        | Yes                                                                                         |
| Internal connections between SPORT halves | Yes. Only Clock and/or Frame Sync can be loopbacked internally between paired SPORT halves. |
| Interrupt Control                         | Yes                                                                                         |
| Protocol                                  |                                                                                             |
| Master Capable                            | Yes                                                                                         |
| Slave Capable                             | Yes                                                                                         |
| Transmission Simplex                      | Yes                                                                                         |
| Transmission Half Duplex                  | Yes                                                                                         |
| Transmission Full Duplex                  | No. The paired SPORT halves can however, be effectively used for full-duplex communication. |

**Table 26-1:** SPORT Specifications (Continued)

| Feature          | Availability                                                                |
|------------------|-----------------------------------------------------------------------------|
| Access Type      |                                                                             |
| Data Buffer      | Yes. Each SPORT half has its own set of control registers and data buffers. |
| Core Data Access | Yes                                                                         |
| DMA Data Access  | Yes                                                                         |
| DMA Channels     | One per SPORT half                                                          |
| DMA Chaining     | Yes                                                                         |
| Boot Capable     | No                                                                          |
| Local Memory     | No                                                                          |
| Clock Operation  | See data sheet                                                              |

## Features

An individual SPORT module consists of two independently configurable SPORT halves with identical functionality. These SPORT halves offer the following features.

- Two bidirectional data lines—Primary (0) and Secondary (1) per SPORT half, configurable as either transmitters or receivers. Therefore, each SPORT half can be configured for two transmitter or two receiver channels, permitting two unidirectional streams into or out of the same SPORT half. This bidirectional functionality provides greater flexibility for serial communications. Further, two SPORT halves can be combined to enable full-duplex, dual-stream communications.
- Six operation modes
  - a. Standard DSP serial mode
  - b. I<sup>2</sup>S mode
  - c. Left-Justified mode
  - d. Right-Justified Mode
  - e. Multichannel Mode
  - f. Packed mode

- Improved granularity for internal clock generation, allowing both even and odd SCLK to SPORT\_CLK ratios. If both data lines of a SPORT half are active, it can have a maximum throughput of 2 x SPORT\_CLK. The SPORTs can accept an input clock from an external source.
- Configurable rising or falling edge of the SPORT\_CLK for driving or sampling data and frame sync.
- Gated clock mode support for both internal clock and external clock mode in DSP serial mode and stereo modes (Left-justified and I<sup>2</sup>S mode).
- Operates with or without a frame synchronization signal for each data word, with internally generated or externally generated frame signals, with active high or active low frame signals, and with either of two configurable pulse widths and frame signal timing.
- Status flagging and optional interrupt generation for prematurely received external frame syncs.
- External frame sync signal can be configured as level-sensitive or edge-sensitive signal.
- Serial data words between 4 and 32 bits in length, either in most significant bit (MSB) first or in least significant bit (LSB) first format. Optional sign-extension on received data.
- Optional 16-bit to 32-bit word packing when SPORT is configured as receiver and 32-bit to 16-bit word unpacking when configured as Transmitter.
- When configured as transmitter, both primary and secondary data paths can have optional compress engines enabled. Similarly, in receiver mode, both paths can have optional have expand engines enabled. A-law and  $\mu$ -law compression/decompression hardware companding according to G.711 specification on transmitted and received words in all operating modes.
- Status flagging and optional interrupt generation for Transmit under-run or Receive over-flow.
- Supports multichannel mode for TDM interfaces. Each SPORT half can transmit or receive data selectively from a time-division-multiplexed serial bit stream on 128 contiguous channels from a stream of up to 1024 total channels. This mode can be useful for H.100/H.110 and other telephony interfaces as a network communication scheme for multiple processors.
- Performs interrupt-driven, single word transfers to and from on-chip or off-chip memory under processor control.
- Dedicated DMA channel for each SPORT half. This DMA is common for both data lines and can be configured for multiple work units such as auto-buffer based (for a repeated, identical range of transfers) or descriptor-based (individual or repeated ranges of transfers with differing DMA parameters).
- SPORT DMA's can be programmed to accept the incoming trigger when configured as Trigger Slave and are capable of generating outgoing trigger as well.
- When using DMA in transmit mode, a Transfer Finish Interrupt (TFI) can be used to make sure that the last word of the transfer has been shifted out of the transmit shift register.
- SPMUX, a local multiplexing block integrated between the SPORT and the PinMux logic, provides the ability to route and share the clocks and/or frame sync between the SPORT halves of the SPORT

module. The internal routing helps to reduce the total number of processor pins required for the interface. This is especially efficient when a SPORT is used for full-duplex data transfers.

- Interface with the ADC Control Module (ACM) block. This allows the frame sync and clock signals generated from ACM block to be routed internally to one of the SPORT halves of SPORT1.

## Signal Descriptions

Each SPORT half module has five dedicated pins, as described in the following table. The actual pin name varies with different SPORT halves. The individual SPORT half does not share any of its pins across the pair. However, if required, clock and frame sync signals can be interconnected between the SPORT half pair, as explained in SPORT pin MUX section.

All the SPORT signals are available on Port B, D, E, G and are multiplexed with other peripheral signals. By default, these pins are in GPIO mode. To enable the pins for SPORT functionality, the appropriate bits must be set in the `PORTx_FER` and `PORTx_MUX` registers. It is advised to configure `PORTx_MUX` register before `PORTx_FER`.

**Table 26-2:** SPORT Pin Descriptions

| Internal Node | Direction | Description                                                                                                                                                                                                                                                            |
|---------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SPORT_CLK     | I/O       | Transmit/Receive Serial Clock. Data and Frame Sync are driven/sampled with respect to this clock. This signal can be either internally or externally generated.                                                                                                        |
| SPORT_FS      | I/O       | Transmit/Receive Frame Sync. The frame sync pulse initiates shifting of serial data. This signal is either generated internally or externally.                                                                                                                         |
| SPORT_D0      | I/O       | Transmit/receive Primary Data channel. Bidirectional data pin. This signal can be configured as an output to transmit serial data, or as an input to receive serial data.                                                                                              |
| SPORT_D1      | I/O       | Transmit/receive secondary Data channel. Bidirectional data pin. This signal can be configured as an output to transmit serial data, or as an input to receive serial data.                                                                                            |
| SPORT_TDV     | O         | Multichannel Transmit Data Valid. This signal is only active if SPORT is configured in multichannel transmit mode. The signal is asserted during enabled slots based on the channel selection registers ( <code>SPORT_CS0_A</code> through <code>SPORT_CS3_B</code> ). |

The signals are known as Transmit signal when the serial port is configured in transmit mode (`SPORT_CTL_A.SPTRAN = 1`); while are known as Receive signals when configured in receive mode (`SPORT_CTL_A.SPTRAN = 0`). These SPORT signals are described in the sections below.

## Serial Clock

The serial port clock (SPORT\_ACLK) signal is considered a Receive serial clock if the transfer direction is configured as receiver; while it is considered a Transmit serial clock when configured as transmitter.

The serial clock (SPORT\_ACLK) is one of the control signal of serial port depending on which the data bits are shifted-in or shifted-out serially based on the direction selected. The frame sync signal is also driven (in internal frame sync mode) or sampled (in external frame sync mode) with respect to serial clock signal. The serial clock can be internally generated from processor's system clock (SCLK1) or externally provided, based on SPORT\_CTL\_A.ICLK bit setting.

If a SPORT is configured in internal clock mode (SPORT\_CTL\_A.ICLK = 1), then the SPORT\_DIV\_A.CLKDIV field specifies the divider to generate serial port clock signal from its fundamental clock, SCLK1. This divisor is a 16-bit value, allowing a wide range of serial clock rates. Use the following equation to calculate the serial clock frequency:

$$\text{SPORT\_ACLK} = [\text{SCLK1} \div (\text{SPORT\_DIV\_A.CLKDIV} + 1)]$$

Use the following equation to determine the value of SPORT\_DIV\_A.CLKDIV, given the SCLK1 frequency and desired serial port clock frequency:

$$\text{SPORT\_DIV\_A.CLKDIV} = [(\text{SCLK1} \div \text{SPORT\_ACLK}) - 1]$$

This equation results in improved granularity for internal clock generation, allowing both odd and even SCLK1:SPORT\_ACLK ratios.

It also supports 1:1 SPORT\_ACLK to SCLK1 ratio, when CLKDIV field is programmed to zero, resulting in serial port clock frequency equal to system clock. But caution must be exercised not to exceed the maximum SPORT\_ACLK frequency specified in the data sheet. Therefore if SCLK1 is greater than the data sheet limit, SPORT\_ACLK:SCLK1 ratio must be limited to 1:2. For other SCLK1 frequencies, this ratio can be programmed up to 1:1.

In certain operating modes, the serial port can be configured to generate gated clock which is active only for the duration of valid data. In some applications, it can be used to generate a general-purpose clock in the system. In this case the SPORT must be enabled with appropriate SPORT\_DIV\_A.CLKDIV divisor field in internal clock mode.

If a SPORT is configured in external clock mode (SPORT\_CTL\_A.ICLK = 0), then serial clock is a input signal making the SPORT to operate in slave mode. The SPORT\_DIV\_A.CLKDIV is ignored. The optional loopback capability provided by SPMUX block, allows slave SPORT to use the serial clock from the neighboring serial port.

The external serial clock can be of the order of system clock1, considering 83 MHz as the maximum SPORT clock frequency. Note that externally supplied serial clock need not be in synchronous with processor system clock. Further, the external clock can be a gated clock but it must comply the requirements described in Gated Clock Mode section. Please refer appropriate product data sheet for exact a.c. timing specifications.

## Frame Sync

The serial port frame sync (SPORT\_AFS) signal is considered a Receive Frame Sync if the transfer direction is configured as receiver; while it is considered a Transmit Frame Sync when configured as transmitter.

Frame sync is also a control signal, generally used to determine the start of new word or frame. Upon detecting this signal, serial port starts shifting in or out the new data bits serially based on the direction selected. The frame sync signal can be internally generated from its serial clock (SPORT\_ACLK) or externally provided, based on the SPORT\_CTL\_A.IFS bit setting.

If SPORT is configured for internal frame sync mode (SPORT\_CTL\_A.IFS = 1), then the SPORT\_DIV\_A.FSDIV field specifies the divider to generate SPORT\_AFS signal from the serial clock. This divisor is a 16-bit value, allowing a wide range of frame sync rates to initiate periodic transfers. The serial clock may be internally generated or externally supplied and it is counted equal to divisor specified before a frame sync pulse is generated. The formula for the number of cycles between frame sync pulses is:

Number of serial clocks between frame syncs = (SPORT\_DIV\_A.FSDIV + 1)

Use the following equation to determine the value of SPORT\_DIV\_A.FSDIV, given the serial clock frequency and desired frame sync frequency:

$$\text{SPORT\_DIV\_A.FSDIV} = [(\text{SPORT\_ACLK} \div \text{SPORT\_AFS}) - 1]$$

The frame sync is continuously active when SPORT\_DIV\_A.FSDIV = 0. The value of SPORT\_DIV\_A.FSDIV should not be less than the serial word length minus one (the value of the SPORT\_CTL\_A.SLEN bit field), as this may cause an external device to abort the current operation or cause other unpredictable results. *After enabling the SPORT, the first internal frame sync appears after a delay of (SPORT\_DIV\_A.FSDIV + 3) serial clocks.*

If a SPORT is configured in external frame sync mode (SPORT\_CTL\_A.IFS = 0), then SPORT\_AFS is a input signal and the SPORT\_DIV\_A.FSDIV field of the SPORT\_DIV\_A register is ignored. By default, this external signal is level-sensitive, but can be configured as an edge-sensitive signal by setting SPORT\_CTL\_A.FSED bit. The frame sync is expected to be synchronous with the serial clock. If not, it must meet the timing requirements that appear in the product specific data sheet.

The serial port can be used as a counter for dividing an external clock to generate periodic pulses or periodic interrupts. The SPORT must be enabled with appropriate SPORT\_DIV\_A.FSDIV divisor field in external clock, internal data-independent frame sync mode.

In some of the operating modes, the serial port can be programmed to treat the frame sync signal as an optional signal by clearing the SPORT\_CTL\_A.FSR bit (it can be used to start the continuous transfers and subsequently ignored). Characteristics of the frame sync depend on the settings in the SPORT control registers and the SPORT's operating mode. For more information, refer to the SPORT control register bits and respective operating mode details.

## Data Signals

Each SPORT half has two bi-directional data lines known as the primary transmit or receive data channel (SPORT\_ADO) and the secondary transmit or receive data channel (SPORT\_AD1). Both the data lines can be configured as either transmitters or receivers using the SPORT\_CTL\_A.SPTRAN bit, permitting dual unidirectional data streams to increase the data throughput of the serial port.

Both data lines can be individually enabled or disabled using the SPORT\_CTL\_A.SPENPRI and the SPORT\_CTL\_A.SPENSEC bits. However, if using both, it is advised to enable or disable them concurrently. They do not behave as totally separate SPORTs; rather, they operate in a synchronous manner (sharing a clock and frame sync) but on separate data paths. All of the SPORT control settings are common for both channels but the single DMA channel per serial half serves both primary and secondary data channels. Also, both primary and secondary channels have separate data buffers, shift registers and optional companding logic in their path.

When a serial port is configured in multichannel transmit mode, the data pins three-states during inactive channel slots. This allows multiple serial port transmitters to operate on the same bus with different active channels.

See the Architecture section for more details about data transfer operation.

## Transmit Data Valid Signal

The Transmit Data Valid (SPORT\_ATDV) signal is available only in multichannel modes (including packed mode) of a SPORT configured as a transmitter. This signal is active during transmission of enabled multichannel slots and remains in an inactive state for the disabled channels. In other words, the SPORT\_ATDV signal is active whenever a serial port is driving the data pins and stays inactive when the data pins three-states. Therefore the SPORT\_ATDV signal can serve as an output-enable signal for the data transmit pin.

## Functional Description

The following section provides general information about functionality of the serial ports of processors.

- [\*Architectural Concepts\*](#)
- [\*Data Types and Companding\*](#)
- [\*Transmit Path\*](#)
- [\*Receive Path\*](#)

## SPORT Register List

The serial port SPORT controller, with its range of clock and frame synchronization options, supports a variety of serial communication protocols and provides a glue-less hardware interface to many industry-standard data converters and CODECs. Each SPORT has two independent halves (A and B), and each half contains two channels (primary and secondary). A set of registers govern SPORT operations. For more information on SPORT functionality, see the SPORT register descriptions.

**Table 26-3:** SPORT Module Registers

| Name          | Description                                         |
|---------------|-----------------------------------------------------|
| SPORT_CTL_A   | Half SPORT 'A' Control Register                     |
| SPORT_DIV_A   | Half SPORT 'A' Divisor Register                     |
| SPORT_MCTL_A  | Half SPORT 'A' Multi-channel Control Register       |
| SPORT_CS0_A   | Half SPORT 'A' Multi-channel 0-31 Select Register   |
| SPORT_CS1_A   | Half SPORT 'A' Multi-channel 32-63 Select Register  |
| SPORT_CS2_A   | Half SPORT 'A' Multi-channel 64-95 Select Register  |
| SPORT_CS3_A   | Half SPORT 'A' Multi-channel 96-127 Select Register |
| SPORT_ERR_A   | Half SPORT 'A' Error Register                       |
| SPORT_MSTAT_A | Half SPORT 'A' Multi-channel Status Register        |
| SPORT_CTL2_A  | Half SPORT 'A' Control 2 Register                   |
| SPORT_TXPRI_A | Half SPORT 'A' Tx Buffer (Primary) Register         |
| SPORT_RXPRI_A | Half SPORT 'A' Rx Buffer (Primary) Register         |
| SPORT_TXSEC_A | Half SPORT 'A' Tx Buffer (Secondary) Register       |
| SPORT_RXSEC_A | Half SPORT 'A' Rx Buffer (Secondary) Register       |
| SPORT_CTL_B   | Half SPORT 'B' Control Register                     |
| SPORT_DIV_B   | Half SPORT 'B' Divisor Register                     |
| SPORT_MCTL_B  | Half SPORT 'B' Multi-channel Control Register       |
| SPORT_CS0_B   | Half SPORT 'B' Multi-channel 0-31 Select Register   |

**Table 26-3:** SPORT Module Registers (Continued)

| Name          | Description                                        |
|---------------|----------------------------------------------------|
| SPORT_CS1_B   | Half SPORT 'B' Multi-channel 32-63 Select Register |
| SPORT_CS2_B   | Half SPORT 'B' Multichannel 64-95 Select Register  |
| SPORT_CS3_B   | Half SPORT 'B' Multichannel 96-127 Select Register |
| SPORT_ERR_B   | Half SPORT 'B' Error Register                      |
| SPORT_MSTAT_B | Half SPORT 'B' Multi-channel Status Register       |
| SPORT_CTL2_B  | Half SPORT 'B' Control 2 Register                  |
| SPORT_TXPRI_B | Half SPORT 'B' Tx Buffer (Primary) Register        |
| SPORT_RXPRI_B | Half SPORT 'B' Rx Buffer (Primary) Register        |
| SPORT_TXSEC_B | Half SPORT 'B' Tx Buffer (Secondary) Register      |
| SPORT_RXSEC_B | Half SPORT 'B' Rx Buffer (Secondary) Register      |

## ADSP-BF60x SPORT Interrupt List

**Table 26-4:** ADSP-BF60x SPORT Interrupt List

| Description             | ID | DMA Channel | Sensitivity |
|-------------------------|----|-------------|-------------|
| SPORT0 Channel A DMA    | 43 | 0           | LEVEL       |
| SPORT0 Channel A Status | 44 |             | LEVEL       |

## Block Diagram

The serial port is configured in transmit mode, if `SPORT_CTL_A.SPTRAN` control bit is set. If this bit is cleared, serial port configures in receive mode. If `SPORT_CTL_A.SPENPRI` control bit is set, then serial port activates primary transmit/receive path. If `SPORT_CTL_A.SPENSEC` control bit is set, then it activates secondary transmit/receive path. Both data channels can be enabled to allow synchronous dual-stream communication. Each path optionally supports Hardware companding or expanding as well. Once a path is activated, data is shifted in response to a frame sync at the rate of serial clock. Inactive data buffers are not used and should not be accessed. An application program must use the appropriate data buffers.

These serial ports are not UARTs and cannot communicate with an RS-232 device or any other asynchronous communications protocol. One way to implement RS-232 compatible communication with the processor is to use two of the FLAG pins as asynchronous data receive and transmit signals.

The following figure shows a detailed block diagram of a SPORT half side.

**Figure 26-1:** Serial Port Block Diagram

## Architectural Concepts

Each SPORT module consists of two separate blocks, known as half-SERIAL PORT (HSPORT) A and B, with identical functionality. These blocks can be independently configurable as either transmitter or receiver; and optionally coupled together internally in a limited way. Each HSPORT also supports two synchronous bidirectional data paths, referred as primary (D0) and secondary (D1) data lines, as shown in the following figure.

**Figure 26-2:** Top Level SPORT Diagram

Each HSPORT can be configured as either transmitter or receiver, according to which the pair of data signals transmit or receive data bits synchronously. The `SPORT_CTL_A.SPTRAN` bit controls the direction for both data paths of the HSPORT. Each HSPORT has its own set of control registers and data buffers grouped per SPORT module. The dual data signals of each HSPORT cannot transmit and receive the data simultaneously for full-duplex operation. Two HSPORTs must be combined to achieve full-duplex operation.

Serial communications are synchronized to the serial clock signal. Every data bit must be accompanied by a clock pulse. Each serial port can internally generate its own serial clock signal from the processor's system clock using the divisor field of the `SPORT_DIV_A.FSDIV` bit field. If programmed, serial ports can also operate in external clock mode. Both primary and secondary data channels shift data based on `SPORT_CLK` rate and the `SPORT_CTL_A.CKRE` bit

In addition to the serial clock signal, data may be signaled by a frame synchronization signal. The framing signal can occur at the beginning of an individual word or at the beginning of a block of words. The configuration of frame sync signal depends upon the type of serial device connected to the processor. Each serial port can generate its own frame sync signal (`SPORT_FS`) depending on the bit settings of SPORT control register. An internally generated frame sync is derived from the SPORT clock using the divisor field of the `SPORT_DIV_A.FSDIV` bit field. Serial ports can also accept external `SPORT_FS` signal. Both primary and secondary data paths starts shifting data after detecting a valid frame sync signal according to control bit settings and operating mode of serial port. A variety of serial data communication protocols can be

emulated according to the frame sync format. All frame sync options are available whether the signal is generated internally or externally generated.

## Multiplexer Logic

There is a local muxing block, known as SPMUX, that is integrated between the SPORT and the PinMux logic of processor. It allows flexibility to route and share the clock and frame sync signals between the SPORT half pair of a SPORT. This is where the two independent SPORT halves of a SPORT can be coupled together. This feature can be used to reduce the total number of pins for the interface and is considered to be efficient when the SPORT half pair is used for full-duplex operation.

The SPORT\_CTL2\_A register is used to configure this loopback feature. The control bits of this register are as described in the "Register Descriptions" section of this chapter.

The multiplexing depends on the SPORT\_CTL\_A.IFS and SPORT\_CTL\_A.ICLK bit settings of the and is further controlled by the SPORT\_CTL2\_A.CKMUXSEL and SPORT\_CTL2\_A.FSMUXSEL bit settings of the SPORT half pair. The following two tables show the valid combinations for the SPORT\_CTL\_A.IFS, SPORT\_CTL\_A.ICLK, SPORT\_CTL2\_A.CKMUXSEL and SPORT\_CTL2\_A.FSMUXSEL bit settings. All other settings are considered to be illegal. The illegal settings, however, are not checked or prevented by hardware. Programs should ensure that only legal combinations are used.

The table's Routing column uses the following abbreviations.

- HSx\_FI = Frame sync input. It can be provided by external device or by the neighboring SPORT half.
- HSx\_FO = Frame sync output. When SPORT is configured in internal frame sync mode.
- SPx\_FS = signal appearing on frame sync pin of the SPORT half.

*In the tables, the Half-SPORT pair of a SPORT, A and B, are referred as HS0 and HS1 and are applicable for all SPORTs.*

**Table 26-7:** Frame Sync Combinations

| FS Combination ID | HS0_IFS | HS1_IFS | FS0MUX | FS1MUX | Routing                             |
|-------------------|---------|---------|--------|--------|-------------------------------------|
| 1                 | 0       | 0       | 0      | 0      | Native FS Operation                 |
| 2                 | 0       | 1       | 0      | 0      | Native FS Operation                 |
| 3                 | 1       | 0       | 0      | 0      | Native FS Operation                 |
| 4                 | 1       | 1       | 0      | 0      | Native FS Operation                 |
| 5                 | 0       | 0       | 1      | 0      | HS0_FI ≤ SP1_FS;<br>HS1_FI ≤ SP1_FS |

**Table 26-7:** Frame Sync Combinations (Continued)

| FS Combination ID | HS0_IFS | HS1_IFS | FS0MUX | FS1MUX | Routing                                            |
|-------------------|---------|---------|--------|--------|----------------------------------------------------|
| 6                 | 0       | 1       | 1      | 0      | $HS0\_FI \leq HS1\_FO \geq SP1\_FS$                |
| 7                 | 0       | 0       | 0      | 1      | $HS1\_FI \leq SP0\_FS$ ;<br>$HS0\_FI \leq SP0\_FS$ |
| 8                 | 1       | 0       | 0      | 1      | $HS1\_FI \leq HS0\_FO \geq SP0\_FS$                |

The table's Routing column uses the following abbreviations.

- $HSx\_CI$  = serial clock input. It can be provided by external device or by neighboring SPORT half.
- $HSx\_CO$  = serial clock output. When SPORT is configured in internal clock mode.
- $SPx\_CLK$  = signal appearing on serial clock pin of the SPORT half.

**Table 26-8:** Clock Combinations

| CLK Combination ID | HS0_ICLK | HS1_ICLK | CK0MUX | CK1MUX | Routing                                              |
|--------------------|----------|----------|--------|--------|------------------------------------------------------|
| 9                  | 0        | 0        | 0      | 0      | Native CLK Operation                                 |
| 10                 | 0        | 1        | 0      | 0      | Native CLK Operation                                 |
| 11                 | 1        | 0        | 0      | 0      | Native CLK Operation                                 |
| 12                 | 1        | 1        | 0      | 0      | Native CLK Operation                                 |
| 13                 | 0        | 0        | 1      | 0      | $HS0\_CI \leq SP1\_CLK$ ;<br>$HS1\_CI \leq SP1\_CLK$ |
| 14                 | 0        | 1        | 1      | 0      | $HS1\_CI \leq HS1\_CO \geq SP1\_CLK$                 |
| 15                 | 0        | 0        | 0      | 1      | $HS1\_CI \leq SP0\_CLK$ ;<br>$HS0\_CI \leq SP0\_CLK$ |
| 16                 | 1        | 0        | 0      | 1      | $HS1\_CI \leq HS0\_FO \geq SP0\_CLK$                 |

The following additional points on these combination settings should be noted.

- FS IDs 1–4 are supported with all CLK IDs 9–16.
- FS ID 5 is only supported with CLK ID 13 and vice-versa.

- FS ID 6 is only supported with CLK ID 14 and vice-versa.
- FS ID 7 is only supported with CLK ID 15 and vice-versa.
- FS ID 8 is only supported with CLK ID 16 and vice-versa.
- CLK IDs 9–12 are supported with all FS IDs 1–8.

**NOTE:** From these tables, one can note that a SPORT half can import serial clock signal from paired HSPORT, only when it configured in external clock mode; similarly, it can import frame sync signal, only when it is configured in external frame sync mode. The neighboring SPORT may be master (generates it's own serial clock or frame sync signal) or slave (accepting external clock or external frame sync). It can be also noticed that, SPORT\_CTL2 register programming is required only at the acceptor SPORT half side; and not required at the donor SPORT half side to enable this sharing.

Note that Polarity bits such as SPORT\_CTL\_A.CKRE and SPORT\_CTL\_A.LFS should have identical settings when using muxing between two SPORT halves.

**NOTE:** There are some limitations on use of SPMUX logic when a SPORT is interfaced with an ACM module of the processor. Refer to the ACM chapter for more details.

## Data Types and Companding

The Data Type select field SPORT\_CTL\_A.DTYPE bit specifies one of the four data formats supported by serial ports. These formats can be used in any of the operating mode of serial port.

**Table 26-9:** Data Type Bit Field Settings

| DTYPE field | SPORT Receiver                          | SPORT Transmitter    |
|-------------|-----------------------------------------|----------------------|
| 00          | Right-Justify, zero-fill unused MSB's   | Normal Operation     |
| 01          | Right-Justify, sign-extend unused MSB's | Reserved             |
| 10          | Expand using u-law                      | Compress using u-law |
| 11          | Expand using A-law                      | Compress using A-law |

These formats are applied to data words loaded into the SPORT transmit or receive data buffers. The first two data formats (00 and 01 values of SPORT\_CTL\_A.DTYPE) are applicable only when SPORT is configured as receiver; as when configured as transmitter, only the significant bits are transmitted (as per the field defined in control register). Therefore the transmit data buffers are not actually zero filled or sign extended.

The other two data formats enable the companding logic on the transmit/receive path. Companding (compressing or expanding) is the process of logarithmically encoding and decoding data to minimize the

number of bits to be sent. The processor's SPORTs support the two most widely used companding algorithms, A-law and  $\mu$ -law, which is performed according to the CCITT G.711 specification.

If selected, companding applies to both the enabled data channels. When enabled as SPORT transmitter, writes to transmit buffer causes its content compressed to eight bits (zero filled to the width of the transmit word) according to algorithm selected. Similarly, if configured in receive mode, the received 8-bits in the receive data buffers are expanded in right-justified, zero fill format as per the algorithm selected. If companding is enabled in multichannel mode, it is applied to all the active channels.

The compression for transmit data requires a minimum word length of 8 for proper function. If `SPORT_CTL_A.SLEN` is less than 7, then expansion may not work correctly. Also, if the data value is greater than 13-bit A-law or 14-bit  $\mu$ -law maximum, it is automatically compressed to the maximum value.

**NOTE:** The processor companding logic supports in-place companding feature. So, companding can be used as debug feature without enabling SPORT. See 'Companding as a Function' section for more details.

## Companding as a Function

Since the values in the transmit and receive buffers are actually companded in place, the companding hardware can be used without transmitting (or receiving) any data, for example during testing or debugging. For companding to execute properly, program the SPORT registers prior to loading data values into the SPORT buffers.

To compress data in place without transmitting use the following procedure.

1. Set the serial port as transmitter (`SPORT_CTL_A.SPTRAN = 1`) with both primary and secondary data channels disabled (`SPORT_CTL_A.SPENPRI = SPORT_CTL_A.SPENSEC = 0`).
2. Enable companding in the `SPORT_CTL_A.DTYPE` field.
3. Write a 32-bit data word to the transmit buffer
4. Wait for two system clock cycles. Any instruction not accessing the transmit buffer can be used to cause this delay. This allows the serial port companding hardware to reload the transmit buffer with the companded value.
5. Read the 8-bit compressed value from the transmit buffer.

To expand data in place, use the same sequence of operations with the receive buffer instead of the transmit buffer. When expanding data in this way, set the appropriate serial word length (`SPORT_CTL_A.SLEN`) bit.

## Transmit Path

The `SPORT_CTL_A.SPTRAN` control bit, when set, configures the SPORT in transmit mode. It then enables primary and/or secondary transmit paths, based on the `SPORT_CTL_A.SPENPRI` and `SPORT_CTL_A.SPENSEC` bit settings. Both data paths, primary and secondary, are separate but identical and include Transmit Data Buffer, optional companding logic and a Transmit Shift Register.

The data buffer on primary transmit path is known as Primary Transmit Data Buffer, or `SPORT_TXPRI_A`; while the one on secondary transmit path is known as Secondary Transmit Data Buffer, or `SPORT_TXSEC_A`. The transmit data buffer and output shift register forms a FIFO type of structure. When packing is disabled (`SPORT_CTL_A.PACK = 0`), serial port can hold as many as 3 data; while if packing is enabled (`SPORT_CTL_A.PACK = 1`), it can hold 2 packed data at any given time.

The data to be transmitted on primary and/or secondary channels is written to the `SPORT_TXPRI_A` and `SPORT_TXSEC_A` transmit data buffers respectively. The transmit data buffers can be accessed in core mode through peripheral bus or in DMA mode through DMA bus. The inactive data buffer must not be accessed. This data is optionally compressed in hardware according to selected algorithm and then automatically transferred to transmit shift register. The shift register, clocked by `SPORT_ACLK` signal, then serially shifts out this data on `SPORT_AD0` or `SPORT_AD1` pins, synchronously. If framing signal is used, the `SPORT_AFS` signal indicates the start of the serial word transmission.

When using DMA mode, a single DMA feeds the data buffers of the enabled channels (primary and or secondary). When using both channels, it is required to interleave the data of these channels properly.

*When SPORT is configured in non-multichannel mode as transmitter, the enabled SPORT data pins `SPORT_AD0` and/or `SPORT_AD1` are always driven. When a SPORT channel is enabled, data from Transmit Data Buffer is loaded into Transmit Shift register. The shift register then immediately latches the first bit of data (either LSB or MSB based on the `SPORT_CTL_A.LSBF` bit setting) and not with respect to frame sync. Similarly, if frame sync duration is greater than serial word length, then during inactive serial clock cycles (clock cycles after data transmission in the current frame), the data pins drives first bit of next word to be transmitted which loaded into shift register. This does not cause any problem at the receiver end, as it starts sampling the data pin only after detecting a valid frame sync. In multichannel mode, data pin always three-states during inactive channel slots.*

The serial port provides status of transmit data buffers and also error detection logic for transmit errors such as under-run. Please see the "Error Detection" section for more details.

When a serial port is configured in transmit mode, the receive paths (and hence the Receive Data Buffers and Receive Shift registers on those paths) are deactivated and do not respond to serial clock or frame sync signals. So, reading from an empty Receive Data Buffer may cause core to hang indefinitely.

## Receive Path

The `SPORT_CTL_A.SPTRAN` bit, when cleared, configures the SPORT in receive mode. It then enables primary and/or secondary receive paths, based on the `SPORT_CTL_A.SPENPRI` and `SPORT_CTL_A.SPENSEC` bit settings. Both data paths, primary and secondary, are separate but identical and include a Receive Shift Register, optional companding logic and a Receive Data Buffer.

The data buffer on primary receive path is known as Primary Receive Data Buffer, or `SPORT_RXPRI_A`; while the one on secondary receive path is known as Secondary receive Data Buffer, or `SPORT_RXSEC_A`. The receive paths act like a 3-word deep (32-bit) FIFO because they have two data registers plus an input shift register.

Upon enabling the serial port data channels, the input Shift register shifts in data bits on the SPORT\_ADO and/or SPORT\_AD1 pins, synchronous to the receive clock signal. If framing signal is used, the SPORT\_AFS signal indicates the beginning of the serial word being received. When an entire word is shifted in on the primary and secondary channels, the data is optionally expanded in hardware according to selected algorithm and then automatically transferred to SPORT\_RXPRI\_A and SPORT\_RXSEC\_A.

The Receive Data Buffers can be read in core mode through peripheral bus or in DMA mode through DMA bus. When DMA mode is used a single DMA reads the data buffers of enabled channels (primary and or secondary). When using both channels, it is required to de-interleave the data of these channels properly. The serial port provides the status of Receive Data buffers and also error detection logic for receive errors such as overflow. See the “Error Detection” section for more details.

When a serial port is configured in receive mode, the transmit paths (and the Transmit Data Buffers and Transmit Shift registers on those paths) are deactivated and do not respond to serial clock or frame sync signals. Therefore programs must not try to access them.

## Sampling Edge

The serial port uses two control signals to sample or drive the serial data.

1. Serial clock (SPORT\_ACLK) applies the bit clock for each serial data
2. Frame sync (SPORT\_AFS) divides the incoming data stream into frames.

These control signals can be internally generated or externally provided, determined by the SPORT\_CTL\_A.ICLK and SPORT\_CTL\_A.IFS bit settings.

Data and frame syncs can be sampled on the rising or falling edges of the serial port clock signals. The SPORT\_CTL\_A.CKRE bit controls the sampling edge. By default, when SPORT\_CTL\_A.CKRE = 0, the processor selects the falling edge of SPORT\_ACLK signal for sampling receive data and external frame sync. The receive data and frame sync are sampled on the rising edge of SPORT\_ACLK when SPORT\_CTL\_A.CKRE = 1.

Note that transmit data and internal frame sync signals are driven (change their state) on the serial clock edge that is not selected. By default, (SPORT\_CTL\_A.CKRE = 0) the SPORTs drive data and frame sync signals on the rising edge of the SPORT\_ACLK signal and drives on falling edge when SPORT\_CTL\_A.CKRE = 1.

Therefore transmit and receive functions of any two serial ports connected together should always select the same value for SPORT\_CTL\_A.CKRE so internally-generated signals are driven on one edge and received signals are sampled on the opposite edge.

The serial port which drives serial clock and frame sync is usually called as master while the receiver of clock and frame sync is referred as slave. The following figure shows the typical SPORT signals at two sides of serial communication for SPORT\_CTL\_A.CKRE = 0. The SPORT configured as Transmitter also drives the serial clock and Frame sync signals as a master device.

**Figure 26-3:** Frame Sync and Data Driven on Rising Edge

When slave samples the Frame Sync signal, the `SPORT_CTL_A.SLEN` word counter is reloaded to the maximum setting. Each `SPORT_ACLK` decrements the `SPORT_CTL_A.SLEN` counter until the full frame is received.

Therefore, if the transmitter drives the internal frame sync and data on the rising edge of serial clock, the falling edge should be used by receiver to sample the external frame sync and data, and vice versa.

Premature Frame Sync Error Detection

A SPORT framing signal is used to synchronize transmit or receive data. In external FS mode, any frame sync received when an active frame is in progress is called premature and is invalid.

As an enhancement to processor's serial port, if a premature frame sync is received, the `SPORT_ERR_A.FSERRSTAT` bit is flagged to indicate this framing error. An optional error interrupt can be generated for this event by setting `SPORT_ERR_A.FSERRMSK` bit.

This feature is applicable in all the operating modes of serial port.

**NOTE:** The `SPORT_ERR_A.FSERRSTAT` bit is not set in the presence of uncleared underflow/overflow errors.

In stereo or I<sup>2</sup>S mode, a premature frame sync may result in the SPORT receiving two consecutive left channels or two consecutive right channels and cause channel swapping. In the processor's serial port, swapping of channels due to a premature FS is avoided. If due to premature FS, one data gets corrupted, data will always be dropped in pairs to avoid channel swapping. The premature FS flagging in the error register will be done similarly.

As shown in the following figure, the frame sync error (which sets the error bit) is triggered when an early frame sync occurs during data transfer (transmission or reception) or for late frame sync if the period of the frame sync is smaller than the serial word length (`SPORT_CTL_A.SLEN`).

**Figure 26-4:** Frame Sync Error Detection

When a serial port is receiving or transmitting, its bit count is set to a word length (for example 32 bits). After each clock edge the bit count is decremented. After the word is received/ transmitted, the bit count reaches zero, and on next frame sync it is set to 32. When active transmission or reception is occurring, the bit count value is non-zero. When a frame sync with a bit count of non-zero is detected, a frame sync error occurs.

## Support for Edge-Detected and Level-Sensitive Frame Syncs

The frame sync signal of the SPORT module of earlier Blackfin processors is level-sensitive. Though the level sensitive nature of frame sync will work fine in a noise free environment; but if noise corrupts the signals coming into the SPORT, then there is a chance that the start of frame sync may be missed by the internal logic either because clock getting corrupted or frame sync itself. The frame sync will be sampled from the next clock edge onwards if the frame sync happens to last for more than a bit clock period.

The following figure describes a scenario when an external frame sync signal gets corrupted due to noise and is sampled incorrectly by the slave SPORT module. Consider a frame sync, driven on the rising edge of serial clock at  $t_A$  and expected to be sampled by slave SPORT at the falling edge of serial clock at  $t_B$ . But due to the noise, the first edge of the FS is not seen by the SPORT and samples the FS only at  $t_C$  as shown in the figure. Subsequently the word length counter runs for a period equal to the `SPORT_CTL_A.SLEN` field of the control register and expires at  $t_E$ , instead of correctly at  $t_D$ , receiving incorrect data. Further if a new frame sync edge has come at time  $t_D$ , in level sensitive mode, the SPORT samples this framing signal again only at time  $t_E$ . So, the frame sync sampling continues to be unaligned with the external data.

The enhanced SPORT module provides an option to configure the frame sync signal as edge-sensitive signal. Edge sensitive frame sync detection looks for an edge in an external frame sync for considering it as a valid framing signal. In active-high frame syncs, the rising edge of frame sync is considered valid; while in active-low frame syncs, the falling edge is considered as valid. This optional feature can be activated by programming `SPORT_CTL_A.FSED` (external Frame Sync Edge select) bit.

**NOTE:** `SPORT_CTL_A.FSED` is valid only in External frame sync mode. In internal frame sync mode, this bit is a don't care.

In the example discussed above, consider frame sync configured as edge-sensitive frame sync. In this case, frame sync will not be detected at  $t_E$  because the edge of framing signal had already come the previous cycle ( $t_D$ ) and there is no edge to detect at  $t_E$ . So the word length counter remains idle for this frame, ignoring the incorrect data, and resumes the operation correctly at  $t_F$  when a new edge detects.

This sets the `SPORT_ERR_A.FSERRSTAT` bit and optionally generates a premature FS error interrupt.

**Figure 26-5:** Level-Sensitive Frame Sync Vs. Edge Sensitive Frame Sync

Frame Sync edge detection is used by default for Stereo modes. MCM mode and DSP serial mode have an option to choose between edge detection and normal mode of FS detection.

**NOTE:** When the SPORT is enabled, an already active externally applied frame sync is not allowed to start operation. The SPORT waits for a valid state change from inactive to active for the external frame sync to consider it valid.

## Serial Word Length

The `SPORT_CTL_A.SLEN` field of serial port control register determines the word length of serial data to transmit and receive. Each SPORT half can independently handle word lengths up to 32 bits. The minimum allowable word length depends on operating mode selected. Words smaller than 32 bits are right-justified in the transmit or receive buffers to least significant bit (LSB) position. However, data can be shifted-in or out in MSB first or LSB first format according to `SPORT_CTL_A.LSBF` bit setting. Also, the received word can be sign-extended while storing it in processor memory.

The value of the `SPORT_CTL_A.SLEN` field can be calculated as:

$$\text{SLEN} = \text{Serial port word length} - 1$$

The range of valid word lengths in the operating modes of SPORT are as shown in the following table.

**Table 26-10:** Data Length Versus SPORT Operating Modes

| Mode                    | Serial Port word length (SLEN+1) |
|-------------------------|----------------------------------|
| Standard DSP Serial     | 4–32                             |
| I <sup>2</sup> S        | 5–32                             |
| Left-Justified          | 5–32                             |
| Right-Justified         | 5–32                             |
| Multichannel            | 5–32                             |
| Packed I <sup>2</sup> S | 5–32                             |

**NOTE:** If the companding feature is enabled on the data path, it limits the word length settings. See [Data Types and Companding](#) for more details about word lengths required for companding. If more than 32-bits per frame sync are required to transmit/receive, the multichannel mode can be used (by enabling more than one channel).

## Operating Modes

The SPORTs have six operating modes:

- Standard serial mode
- I<sup>2</sup>S mode
- Left-justified mode
- Right-Justified mode
- Multichannel mode
- Packed I<sup>2</sup>S mode

The SPORT halves within a SPORT can be independently configured in any of these operating modes, unless they are not coupled together using SPMUX logic. Each SPORT half has its own set of control and data registers and are programmed similarly.

The main control register of serial port, SPORT\_CTL\_A, controls the operating modes of the SPORT. The following table lists all the bits of the control register. The SPORT\_CTL\_A register is unique in that the bit function may change depending on the operating mode selected. It should be noted that many bits in the control registers, that control the function of the mode, are the same bit but have a different name depending on the operating mode. The bits common across operating mode columns (for example SPORT\_CTL\_A.SLEN) signifies that they function similarly across those operating modes. However, the bits

divided as per operating modes (for example `SPORT_CTL_A.LFS`) indicate different meaning depending on operating mode. Further, some bits are reserved depending on mode of operation (for example the `SPORT_CTL_A.FSR` bit is reserved in I<sup>2</sup>S, left-justified sample pair, packed I<sup>2</sup>S and in multichannel mode).

**NOTE:** When changing operating modes, clear the serial port control register before the new mode is written to the register.

**Table 26-11:** Control Bits comparison for different operating modes

| Bit (NAME)   | Standard Serial | I2S and<br>Left-Justified | Right-Justified | Multichannel | Packed I2S |
|--------------|-----------------|---------------------------|-----------------|--------------|------------|
| Control Bits |                 |                           |                 |              |            |
| 0 (SPENPRI)  | Yes             |                           |                 |              |            |
| 2–1 (DTYPE)  | Yes             | Reserved                  |                 | Yes          |            |
| 3 (LSBF)     | Yes             | Reserved                  |                 | Yes          |            |
| 8–4 (SLEN)   | Yes             |                           |                 |              |            |
| 9 (PACK)     | Yes             |                           |                 |              |            |
| 10 (ICLK)    | Yes             |                           |                 |              |            |
| 11 (OPMODE)  | Yes             |                           |                 |              |            |
| 12 (CKRE)    | Yes             | Reserved                  |                 | Yes          |            |
| 13 (FSR)     | Yes             | Reserved                  |                 |              |            |
| 14 (IFS)     | Yes             | Reserved                  |                 | Yes          |            |
| 15 (DIFS)    | Yes             |                           |                 | Reserved     |            |
| 16 (LFS)     | Yes             | Yes                       |                 | Yes          | Yes        |
| 17 (LAFS)    | Yes             |                           |                 | Reserved     |            |
| 18 (RJUST)   | Reserved        |                           | Yes             | Reserved     |            |
| 19 (FSED)    | Yes             | Reserved                  |                 | Yes          | Reserved   |
| 20 (TFIEN)   | Yes             |                           |                 |              |            |
| 21 (GCLKEN)  | Yes             |                           | Reserved        |              |            |

**Table 26-11:** Control Bits comparison for different operating modes (Continued)

| Bit (NAME)     | Standard Serial | I2S and<br>Left-Justified | Right-Justified | Multichannel | Packed I2S |
|----------------|-----------------|---------------------------|-----------------|--------------|------------|
| 24 (SPENSEC)   | Yes             |                           |                 |              |            |
| 25 (SPTRAN)    | Yes             |                           |                 |              |            |
| Status Bits    |                 |                           |                 |              |            |
| 26 (DERRSEC)   | Yes             |                           |                 |              |            |
| 28–27 (DXSSEC) | Yes             |                           |                 |              |            |
| 29 (DERRPRI)   | Yes             |                           |                 |              |            |
| 31–30 (DXSPRI) | Yes             |                           |                 |              |            |

## Mode Selection

The serial port operating mode is configured in the SPORT\_CTL\_A and the SPORT\_MCTL\_A registers. The following table provides values for each of the bits in the SPORT serial control registers that must be set in order to configure a specific SPORT operation mode. The shaded columns indicate that the bits come from different control registers.

**Table 26-12:** SPORT Operating Modes

| Operating Modes              | OPMODE (11) | LAFS (17) | RJUST (18) | Multichannel Control Register (SPORT_MCTL_A) |
|------------------------------|-------------|-----------|------------|----------------------------------------------|
| Standard DSP Serial          | 0           | Valid     | 0          | 0                                            |
| I2S                          | 1           | 0         | 0          | 0                                            |
| Left-Justified               | 1           | 1         | 0          | 0                                            |
| Right-Justified              | 1           | 1         | 1          | 0                                            |
| Multichannel                 | 0           | x         | 0          | 1                                            |
| Packed I <sup>2</sup> S mode | 1           | x         | 0          | 1                                            |

The following sections provide detailed information on each operating mode available using the serial ports.

## Standard Serial Mode

The SPORT can be configured in standard DSP serial mode by clearing the `SPORT_CTL_A.OPMODE` and `SPORT_MCTL_A.MCE` bits. The standard serial mode lets programs configure serial ports for use by a variety of serial devices such as serial data converters and audio codecs. In order to connect to these devices, a variety of clocking, framing, and data formatting options are available.

### Timing Control Bits

Several bits in the serial port control register enable and configure standard serial mode operation.

- **SLEN:** serial word length select (4-32 bits)
- **LSBF:** little endian Vs big endian serial bit format
- **ICLK:** Internal clock generation Vs external clock mode
